Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

**Table D-42. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Diesel Particulate Matter (DPM), 2050**

Yuma, AZ	PM10 (1987 24-hour)	Nonattainment, Moderate	100	0	0.00	0.00	0.00

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-43. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Formaldehyde, 2035

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:  
<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.  
<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.  
<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.  
 NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

**Table D-46. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Particulate Matter (PM2.5), 2050**

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-47. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Sulfur Oxides (SO<sub>2</sub>), 2035

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

**Table D-48. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Sulfur Oxides (SO<sub>2</sub>), 2050**

				No-Action	PC1LT3 + HDPUV4	PC2LT4 + HDPUV10	PC6LT8 + HDPUV14
Yuba City-Marysville, CA	PM2.5 (2006 24-hour)	Maintenance, Moderate	100	0	0.00	-0.05	-0.43
Yuma, AZ	Ozone (2015 8-hour)	Nonattainment, Marginal	100	0	0.00	-0.03	-0.30
Yuma, AZ	PM10 (1987 24-hour)	Nonattainment, Moderate	100	0	0.00	-0.05	-0.46

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-49. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Nitrogen Oxides (NO<sub>x</sub>), 2035

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-51. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Volatile Organic Compounds (VOCs), 2035

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickups trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-53. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Carbon Monoxide (CO), 2035

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:  
<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.  
<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.  
<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.  
 NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-59. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Benzene, 2035

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-61. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—1,3-Butadiene, 2035

Notes:  
<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.  
<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.  
<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.  
 NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-62. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—1,3-Butadiene, 2050

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-63. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Diesel Particulate Matter (DPM), 2035

Notes:  
<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.  
<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.  
<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.  
 NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

**Table D-64. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Diesel Particulate Matter (DPM), 2050**

Yuma, AZ	PM10 (1987 24-hour)	Nonattainment, Moderate	100	0	0.00	0.00	0.00

Notes:

<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.

NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

Table D-65. Changes in Emissions from U.S. Combined Passenger Cars, Light Trucks, and HDPUVs by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Formaldehyde, 2035

Notes:  
<sup>a</sup> Nonattainment or maintenance status as of 1/31/2023. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.  
<sup>b</sup> Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.  
<sup>c</sup> Positive values are emissions increases; negative values are emissions decreases.  
 NAAQS = National Ambient Air Quality Standard; CFR = Code of Federal Regulations; CO = carbon monoxide; HDPUV = heavy-duty pickup trucks and vans; NO<sub>2</sub> = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO<sub>2</sub> = sulfur dioxide

## **APPENDIX E**

# **Greenhouse Gas Emissions and Climate Change**

## APPENDIX E GREENHOUSE GAS EMISSIONS AND CLIMATE CHANGE

### E.1 Introduction

Section E.1, *Introduction*, discusses NHTSA’s reliance on major international or national scientific assessment reports such as those from the Intergovernmental Panel on Climate Change (IPCC) and the U.S. Global Change Research Program (GCRP) for the assessment of climate change impacts. Even where assessment reports include consensus conclusions of expert authors, uncertainty still exists, as with all assessments of environmental impacts. Section E.1.1, *Uncertainty in the IPCC Framework*, discusses how uncertainty is communicated in the IPCC reports. Section E.1.2, *Climate Change and its Causes*, presents a brief summary of climate change and drivers.

#### E.1.1 Uncertainty in the IPCC Framework

The IPCC reports communicate uncertainty and confidence bounds using commonly understood but carefully defined words in italics, such as *likely* and *very likely*, to represent likelihood of occurrence. The *IPCC Working Group I Sixth Assessment Report Summary for Policymakers* (IPCC WGI AR6) (IPCC 2021a) briefly explains this convention. The *IPCC Guidance Notes for Lead Authors of the IPCC AR5 on Addressing Uncertainties* (IPCC 2010) provides a more detailed discussion of the IPCC treatment of uncertainty. This EIS uses the IPCC uncertainty language (noted in italics) when discussing qualitative environmental impacts on specific resources. The referenced IPCC documents provide a full understanding of the meaning of those uncertainty terms in the context of the IPCC findings. The IPCC WGI AR6 (IPCC 2021b) notes that the two primary uncertainties with climate modeling are model uncertainties and scenario uncertainties.

- **Model uncertainties.** These uncertainties occur when a climate model might not accurately represent complex phenomena in the climate system (see Figure E.1.1-1 for a sample of processes generally represented in climate models). For some processes, the scientific understanding could be limited regarding how to use a climate model to “simulate” processes in the climate system. Model uncertainties can be differentiated into parametric and structural uncertainties.
- **Scenario uncertainties.** These uncertainties arise because of uncertainty in projecting future greenhouse gas (GHG) emissions, concentrations, and forcings (e.g., from solar activity).

Figure E.1.1-1. Some Climate System Processes Included in Climate Models

Source: GCRP 2014  
 GCM = general circulation model

As stated in the IPCC WGI AR6, these types of uncertainties are described by using two metrics for communicating the degree of certainty: confidence in the validity of findings, expressed qualitatively, and quantified measures of uncertainties, expressed probabilistically. The confidence levels synthesize the judgments about the validity of the findings, determined through evaluation of the evidence and the degree of scientific agreement. The qualitative expression of confidence ranges from *very low* to *very high*, with higher confidence levels assigned to findings that are supported by high scientific agreement. The quantitative expression of confidence ranges from *exceptionally unlikely* to *virtually certain*, with higher confidence representing findings supported by robust evidence (Table E.1.1-1). Figure E.1.1-2 demonstrates how the combination of evidence and agreement statements results in confidence level and

shows that the degree of confidence increases as evidence becomes more robust and agreement is greater. Level of confidence is expressed with five qualifiers: *very low*, *low*, *medium*, *high*, or *very high*.<sup>1</sup>

**Table E.1.1-1. Standard Terms to Define the Likelihood of a Climate-Related Event**

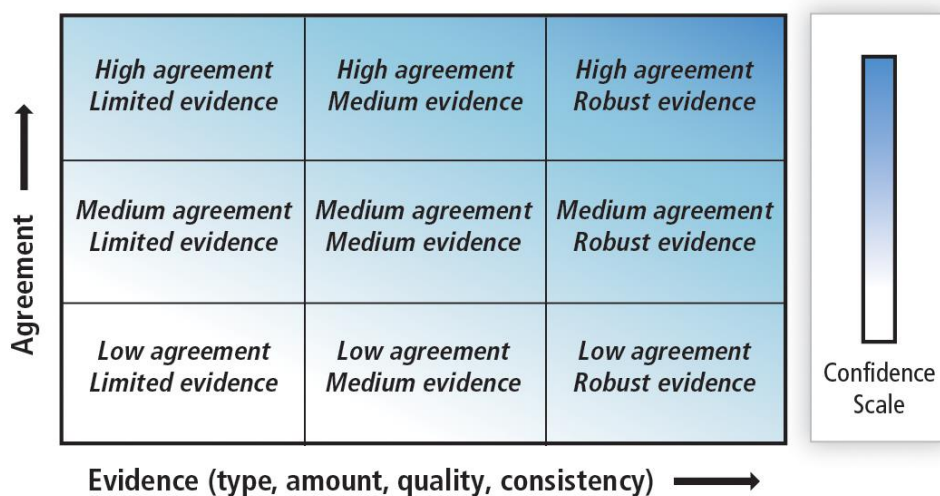

Likelihood Terminology	Likelihood of the Occurrence/Outcome
Virtually certain	99–100% probability
Very likely	90–100% probability
Likely	66–100% probability
About as likely as not	33–66% probability
Unlikely	0–33% probability
Very unlikely	0–10% probability
Exceptionally unlikely	0–1% probability

Notes:

Additional terms that were used in limited circumstances in the IPCC Fifth Assessment Report (AR5) (*extremely likely* = 95–100% probability, *more likely than not* ≥ 50–100% probability, and *extremely unlikely* = 0–5% probability) were also used in IPCC WGI AR6 when appropriate, and in the *Fourth National Climate Assessment* (GCRP 2017).

### E.1.2 Climate Change and Its Causes

Although the climate system is complex, IPCC WGI AR6 identified the following drivers of climate change (Figure E.1.2-1). In 2021, IPCC WGI AR6 evaluated observed changes in these climate system drivers and the effective radiative forcing (ERF) they exert.

- **GHGs.** Primary GHGs in the atmosphere are water vapor, carbon dioxide (CO<sub>2</sub>), nitrous oxide (N<sub>2</sub>O), methane (CH<sub>4</sub>), and ozone (IPCC 2021a). Though most GHGs occur naturally, human activities—

<sup>1</sup> Figure E.1.1-2 shows the relationship between confidence level and summary statements for evidence and agreement. This relationship is flexible and different confidence levels can be assigned for a given evidence and agreement statement (IPCC 2010).

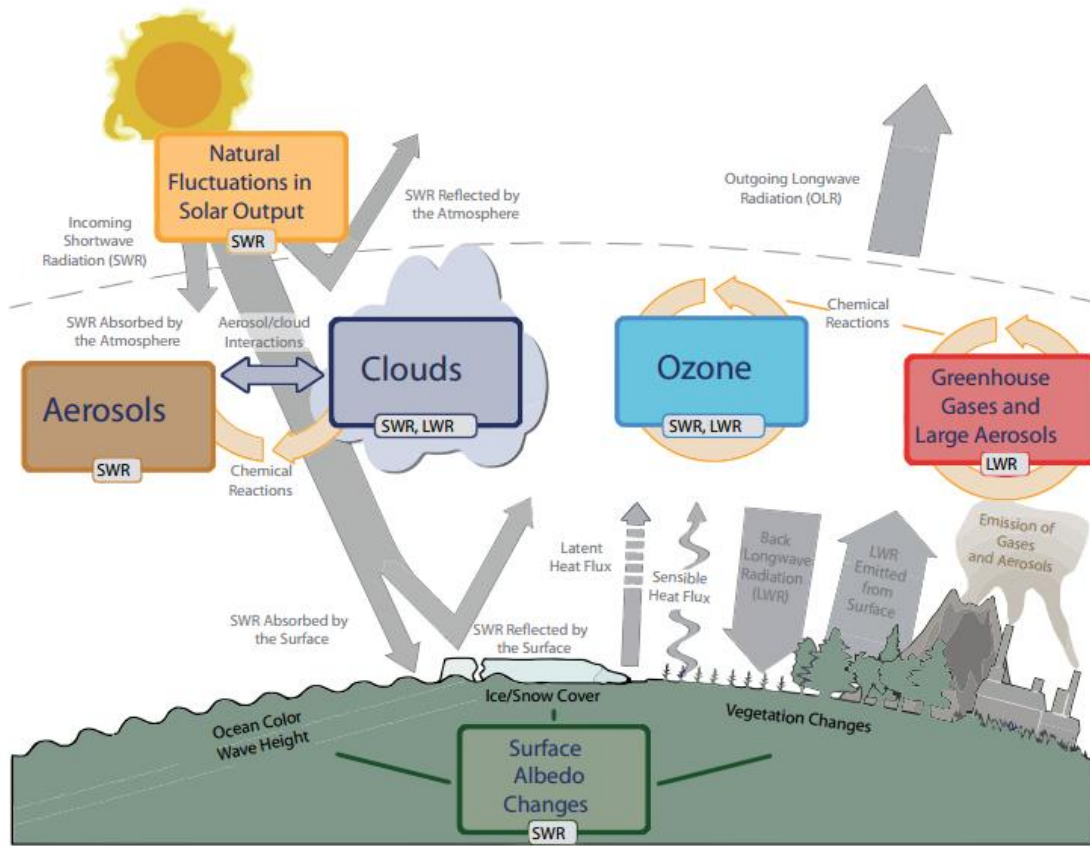

particularly fossil fuel burning—have significantly increased atmospheric concentrations of these gases (see IPCC 2021a for more information on human impacts on the climate and effects of different GHGs).

- **Aerosols.** Aerosols are natural (e.g., from volcanoes) and human-made particles in the atmosphere that scatter incoming sunlight back to space, causing cooling. Some aerosols are hygroscopic (i.e., attract water) and can affect the formation and lifetime of clouds. Large aerosols (more than 2.5 micrometers in size) modify the amount of outgoing long-wave radiation (IPCC 2021a). Other particles, such as black carbon, can absorb outgoing terrestrial radiation, causing warming (IPCC 2021a). In the past 30 years, the relative importance of aerosol forcing compared to other climate drivers has decreased as the net forcing effect of aerosols has continued to decrease in the 21st century (IPCC 2021a).
- **Clouds.** Depending on cloud height, cloud interactions with terrestrial and solar radiation can vary. Any perturbations in cloud fields, such as through aerosol-cloud interactions or through cloud feedbacks, can have strong influences on the energy distribution of the climate system (IPCC 2021a). The rapid adjustments implied by clouds are included in the determination of ERF (IPCC 2021a).
- **Ozone.** Ozone is created through photochemical reactions from natural and human-made gases. In the troposphere, ozone absorbs and re-emits long-wave radiation, acting as a GHG. In the stratosphere, the ozone layer absorbs incoming short-wave radiation (IPCC 2021a). Ozone has the largest positive ERF of all gaseous short-lived climate forcers (IPCC 2021a).
- **Solar radiation.** Solar radiation, the amount of solar energy that reaches the top of Earth’s atmosphere, varies over time (IPCC 2021a). Solar radiation has had a negligible impact on climate change since the start of the industrial era compared to other main drivers (IPCC 2021a).
- **Surface changes.** Changes in vegetation or land surface properties, ice or snow cover, and ocean color can affect surface albedo.<sup>2</sup> The changes are driven by natural seasonal and diurnal changes (e.g., snow cover) as well as human influences (e.g., changes in vegetation type) (IPCC 2021a). Changes to land use and land cover have introduced a negative ERF by increasing surface albedo since 1750 (IPCC 2021a).

---

<sup>2</sup> Surfaces on Earth (including land, oceans, and clouds) reflect solar radiation back to space. This reflective characteristic, known as *albedo*, indicates the proportion of incoming solar radiation the surface reflects. High albedo has a cooling effect because the surface reflects rather than absorbs most solar radiation.

SWR = shortwave radiation; LWR = longwave radiation; OLR = outgoing longwave radiation

## E.2 Greenhouse Gas Emissions and Aerosols—Historical and Current Trends

### E.2.1 Global Greenhouse Gas Emissions

GHGs are gaseous constituents in the atmosphere, both natural and anthropogenic, that absorb and re-emit terrestrial infrared radiation. Primary GHGs in the atmosphere are water vapor, CO<sub>2</sub>, N<sub>2</sub>O, CH<sub>4</sub>, and ozone. These GHGs occur naturally and because of human activity.<sup>3</sup> Other GHGs, such as the fluorinated gases,<sup>4</sup> are almost entirely anthropogenic in origin and are used in commercial applications such as refrigeration and air conditioning and industrial processes such as aluminum production.

By far the GHG with the largest contribution to warming is CO<sub>2</sub>. Global atmospheric CO<sub>2</sub> concentrations have increased 49.2 percent, from approximately 278 parts per million (ppm) in 1750 (IPCC 2021a) to

<sup>3</sup> Although humans have always contributed some level of GHG emissions to the atmosphere through activities like farming and land clearing, substantial anthropogenic contributions did not begin until the mid-1700s with the onset of the Industrial Revolution. People began burning coal, oil, and natural gas to light their homes, power trains and cars, and run factories and industrial operations.

<sup>4</sup> Fluorinated GHGs or gases include perfluorocarbons, hydrofluorocarbons (HFCs), sulfur hexafluoride, and nitrogen trifluoride.

approximately 414.71 ppm in 2021 (National Oceanic and Atmospheric Administration [NOAA] 2023a). Isotopic- and inventory-based studies make clear that this rise in the CO<sub>2</sub> concentration is largely a result of the release of carbon that had been stored underground and then used to combust fossil fuels (coal, petroleum, and natural gas) to produce electricity, heat buildings, and power motor vehicles and airplanes, among other uses (IPCC 2021a). In 2019, CO<sub>2</sub> emissions accounted for 74 percent of global GHG emissions on a global warming potential (GWP)–weighted basis,<sup>5</sup> followed by CH<sub>4</sub> (18 percent), N<sub>2</sub>O (6 percent), and fluorinated gases (2 percent) (World Resources Institute [WRI] 2023).<sup>6</sup> Atmospheric concentrations of N<sub>2</sub>O and CH<sub>4</sub> increased approximately 19 and 158 percent, respectively, over roughly the same period (IPCC 2021a).

GHGs are emitted from a wide variety of sectors, including energy, industrial processes, waste, agriculture, and forestry. The energy sector is the largest contributor of global GHG emissions, accounting for 78 percent of global emissions in 2019; other major contributors of GHG emissions are agriculture (12 percent), industrial processes (6 percent), and waste (3 percent) (WRI 2023). Transportation CO<sub>2</sub> emissions from the combustion of petroleum-based fuels have increased by 74 percent from 1990 to 2019 and account for roughly 14 percent of total global GHG emissions (WRI 2023).<sup>7</sup> The energy sector is largely composed of emissions from fuels consumed in the electric power, transportation, industrial, commercial, and residential sectors. The 14 percent value for transportation is therefore included in the 78 percent value for energy.

In general, global GHG emissions continue to increase, although annual increases vary according to factors such as weather, energy prices, and economics. Observed emissions between 2000 and 2010 approximately track the upper half of Representative Concentration Pathway (RCP)<sup>8</sup> projections while more recently, the global fossil and industrial CO<sub>2</sub> emissions follow the middle of the projected Shared Socioeconomic Pathway (SSP)<sup>9</sup> scenario ranges, though regional differences exist (IPCC 2021a).

---

<sup>5</sup> Each GHG has a different radiative efficiency (i.e., the ability to absorb infrared radiation) and atmospheric lifetime. To compare their relative contributions, GHG emissions quantities are converted to carbon dioxide equivalent using the 100-year time horizon GWP as reported in IPCC's *Fourth Assessment Report (AR4): The Physical Science Basis* (IPCC 2007).

<sup>6</sup> These global GHG estimates *do not* include contributions from land-use change and forestry or international bunker fuels.

<sup>7</sup> The energy sector is largely composed of emissions from fuels consumed in the electric power, transportation, industrial, commercial, and residential sectors. The 14 percent value for transportation is therefore included in the 78 percent value for energy.

<sup>8</sup> The Representative Concentration Pathways (RCPs) were developed for the IPCC AR5 report. They define specific pathways to emissions concentrations and ERF in 2100. The RCPs established four potential emissions concentration futures, a business-as-usual pathway representing continued GHG concentration increases (RCP8.5), two stabilization pathways (RCP6.0, RCP4.5), and an aggressive reduction pathway (RCP2.6).

<sup>9</sup> The Shared Socioeconomic Pathways (SSPs) were developed for the IPCC AR6 report. Similar to RCPs, they utilize global socioeconomic projections to derive time-dependent global GHG concentrations and drive general circulation model simulations of climate change. The SSPs were designed to provide an expanded set of GHG concentration scenarios for the Coupled Model Intercomparison Project Phase 6 based on a range of socioeconomic scenarios, with SSP1 through 5 accounting for various global mitigation and adaptation measures. There is a set of five core SSPs used in IPCC reports: SSP1-1.9, SSP1-2.6, SSP2-4.5, SSP3-7.0, and SSP5-8.5.

## E.2.2 U.S. Greenhouse Gas Emissions

In 2021, U.S. GHG emissions were estimated to be 6,340 million metric tons carbon dioxide equivalent (MMT<sub>CO<sub>2</sub>e</sub>) (EPA 2023a).<sup>10</sup> The United States was the second largest emitter of GHG emissions in 2019 (the most recent year for which global emissions are available), contributing 13.0 percent of global emissions (excluding emissions and sinks from land-use change) (WRI 2023).<sup>11</sup> CO<sub>2</sub> is by far the primary GHG emitted in the United States, representing 79 percent of U.S. GHG emissions in 2021 (EPA 2023a) (on a GWP-weighted basis).

Most GHG emissions in the United States are from the energy sector, with the majority of those emissions being CO<sub>2</sub> emissions from the combustion of fossil fuels. In 2021, CO<sub>2</sub> emissions from fossil fuel combustion alone accounted for 73.2 percent of total U.S. GWP-weighted emissions (EPA 2023a), with the remaining emissions contributed by other energy-related activities (e.g., fugitive emissions from natural gas systems), industrial processes and product use, agriculture, forestry, waste, and other land use. CO<sub>2</sub> emissions due to combustion of fossil fuels are from fuels consumed in the following sectors: transportation (38 percent of fossil fuel combustion CO<sub>2</sub> emissions), electric power (33 percent), industrial (17 percent), residential (7 percent), commercial (5 percent), and U.S. territories (which include all of the aforementioned sectors) (1 percent) (EPA 2023a).

When U.S. CO<sub>2</sub> emissions are apportioned by end use, transportation is the single leading source of U.S. emissions from fossil fuels, causing over one-third of total CO<sub>2</sub> emissions from fossil fuels (EPA 2023a).<sup>12</sup> CO<sub>2</sub> emissions from passenger cars and light trucks accounted for 58 percent of total U.S. CO<sub>2</sub> emissions from transportation in 2021 (EPA 2023a).

From 1990 to 2021, CO<sub>2</sub> emissions from passenger cars and light trucks increased by 12 percent (EPA 2023a). This increase in emissions is attributed to a 44.4 percent increase in vehicle miles traveled (VMT) by light-duty (LD) motor vehicles (passenger cars and light trucks), because of population growth and expansion, economic growth, and low fuel prices (EPA 2023a). Additionally, the rising popularity of sport utility vehicles and other light trucks with lower fuel economy than passenger cars has contributed to higher emissions (EPA 2023a; DOT 2017). However, fuel efficiency for new LD vehicles produced in 2020, including light trucks and sport utility vehicles, reached a record high of 25.6 miles per gallon (mpg) (U.S. Department of Energy [DOE] 2021a).

The coronavirus disease of 2019 (COVID-19) pandemic resulted in a 9 percent decrease in gross U.S. GHG emissions from 2019 to 2020, with contributions by sector remaining relatively consistent (EPA 2023a). Travel restrictions and behavior across the country resulted in decreased VMT by personal vehicles and lightweight trucks by 11 percent from 2019 to 2020 (EPA 2023a). However, due to the increased demand for e-commerce goods, VMT for HD vehicles increased from 2019 to 2020 (DOT 2022). Between 2019 and 2020, CO<sub>2</sub> emissions from passenger cars and light trucks decreased 14 percent; CO<sub>2</sub> emissions from transportation decreased 13 percent.

---

<sup>10</sup> The most recent year for which an official EPA estimate is available, excluding emissions and sinks from land-use change and forestry (EPA 2023a).

<sup>11</sup> Based on global and U.S. estimates for 2019, the most recent year for which a global estimate is available. Excluding emissions and sinks from land-use change and forestry.

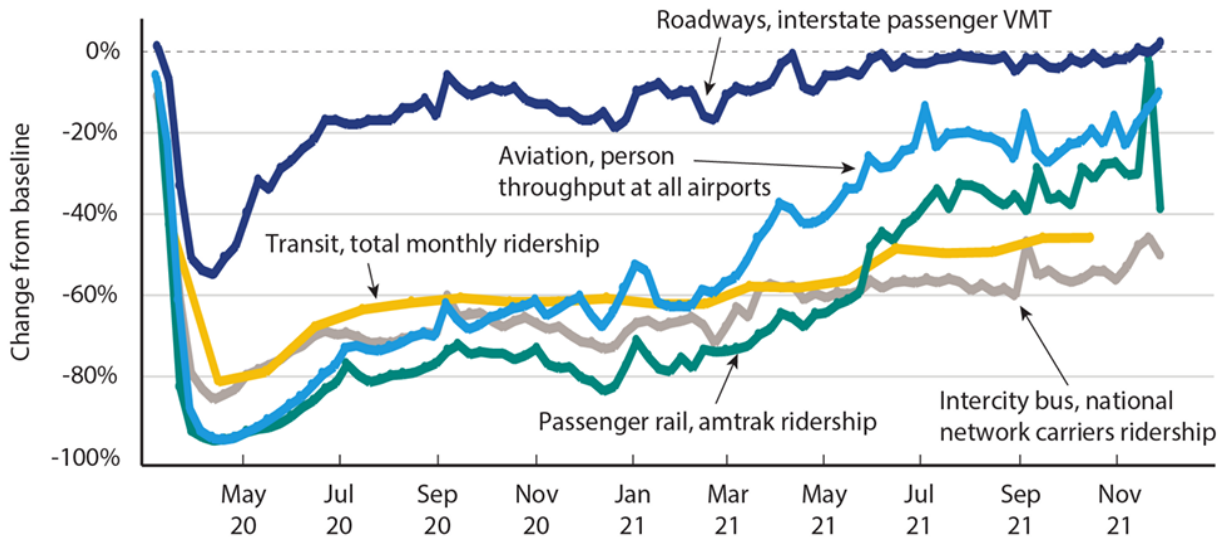

<sup>12</sup> Apportioning by end use allocates emissions associated with electricity generation to the sectors (residential, commercial, industrial, and transportation) where it is used.

More recent data shows that this decrease in emissions was temporary. In the transportation sector, indicators of emissions such as VMT have significantly increased since the end of 2020 as travel restrictions eased and economic activity increased (Liu et al. 2020). VMT increased by 11 percent from 2020 to 2021 (DOT 2021a), despite shifts in travel and behavior compared to before the pandemic (e.g., increases in Americans working from home or hybrid working). Furthermore, between 2020 and 2021, CO<sub>2</sub> emissions from passenger cars and light trucks increased 10 percent; CO<sub>2</sub> emissions from transportation increased 11 percent (EPA 2023a).

Figure E.2.2-1 shows that travel by personal vehicles has returned to, if not exceeded, pre-COVID-19 levels.

**Figure E.2.2-1. Percentage change in Passenger Travel from 2019 by Mode**

VMT = vehicle miles traveled

Figure E.2.2-2 shows the proportion of U.S. CO<sub>2</sub> emissions in 2021 attributable to the transportation sector and the contribution of each mode of transportation to those emissions. The percentages shown in this chart are similar to those from 2020.

Figure E.2.2-2. Contribution of Transportation to U.S. Carbon Dioxide Emissions by Mode (2021)

Source: EPA 2023a

MD/HD= Medium-Duty and Heavy-Duty

Although CO<sub>2</sub> emissions represent the vast majority of the U.S. contribution to warming (79.4 percent), CH<sub>4</sub> accounts for 11.5 percent of U.S. GHGs on a GWP-weighted basis, followed by N<sub>2</sub>O (6.2 percent) and the fluorinated gases (3.0 percent) (EPA 2023a).

### E.2.3 Black Carbon and Other Aerosols

Aerosols are solid or liquid particles suspended in the Earth's atmosphere. The chemical composition of aerosols varies enormously and can include sulfates, nitrates, dust, black carbon, and other chemical species (IPCC 2021a; CCSP 2009). Aerosols are either emitted directly from a source (e.g., power plants, forest fires, volcanoes) into Earth's atmosphere or chemically created in the atmosphere from gases (IPCC 2021a; CCSP 2009). Depending on meteorological conditions and other factors, aerosols typically remain in Earth's atmosphere from days to weeks (IPCC 2021a). Their relatively short lifetimes can create regional areas of high aerosol concentrations nearby as well as some distance downwind from emissions source(s) (IPCC 2021a).

An aerosol's impact on climate depends on its composition. Some aerosols, such as sulfates, reflect incoming sunlight back to space, causing a cooling effect; other aerosols, such as black carbon, absorb incoming sunlight, causing a warming effect (IPCC 2021a; CCSP 2009). In addition, some aerosols attract moisture or water vapor and can affect the lifetime and reflectivity of clouds. Overall, IPCC (2021a) states that there is *high confidence* that aerosols have offset a substantial portion of global mean forcing by cooling Earth's atmosphere from the reflection of incoming sunlight and their interaction with clouds,

though large uncertainties exist. Overall, aerosols can act to intensify precipitation in deep convective clouds or suppress precipitation in shallow cloud regimes through radiative and microphysical processes (IPCC 2021a).

Among the aerosols, black carbon has attracted much attention because of its strong impact on Earth's energy balance. Black carbon is an aerosol that forms during incomplete combustion of certain fossil fuels (primarily coal and diesel) and biomass (primarily fuel wood and crop waste). There is no single accepted method for summarizing the range of effects of black carbon emissions on the climate or representing these effects and impacts in terms of carbon dioxide equivalent (CO<sub>2</sub>e); significant scientific uncertainties remain regarding black carbon's total climate effect. The IPCC (2021a) integrated the overall indirect cloud effects of black carbon (and other light-absorbing particles) into the estimated ERFs on the earth's energy budget, resulting in a small net positive (i.e., warming) (*low confidence*). Quantifiable estimate shows large uncertainties and although black carbon is likely to be a contributor to climate change, it is not feasible to quantify black carbon climate impacts in an analysis of the Proposed Action and alternatives.<sup>13</sup>

LD passenger cars and heavy-duty pickup trucks and vans (HDPUVs) (especially those that are diesel-powered) contribute to U.S. emissions of black carbon. For further information on black carbon and aerosol emissions, climatic interactions, and net radiative effect, see Section 5.1.6 of the *Phase 2 Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles Final EIS* (NHTSA 2016b).

### **E.3 Climate Change Trends**

IPCC concludes that, at continental and global scales, numerous long-term changes in climate have been observed. Additionally, IPCC and the GCRP include the following trends observed over the 20th century as further supporting the evidence of climate-induced changes:

- Most land areas have *very likely* experienced warmer and/or fewer cold days and nights along with warmer and/or more frequent hot days and nights (IPCC 2021a; GCRP 2017).
- Cold-dependent habitats are shifting to higher altitudes and latitudes, and growing seasons are becoming longer (IPCC 2021a; GCRP 2017).
- Sea level is rising, caused by thermal expansion of the ocean water and melting of snowcaps and ice sheets (IPCC 2021a; GCRP 2017).
- More frequent weather extremes such as droughts, floods, severe storms, and heat waves have been observed (IPCC 2021b; GCRP 2017).
- There is *high confidence* that oceans are becoming more acidic because of increasing absorption of CO<sub>2</sub> by seawater, which is driven by a higher atmospheric concentration of CO<sub>2</sub> (IPCC 2021a; United Nations [UN] 2021; GCRP 2017). Recent assessments found that the oceans have become about 30 percent more acidic over the last 150 years since the Industrial Revolution (GCRP 2017).

Developed countries, including the United States, have been responsible for the majority of GHG emissions since the mid-19th century and still have some of the highest GHG emissions per capita (WRI 2023). While annual emissions from developed countries have been relatively flat over the last few decades, world population growth, industrialization, and increases in living standards in developing

---

<sup>13</sup> NHTSA conducted a literature review on black carbon in early 2023, and did not locate new sources that met the criteria for inclusion in this document.

countries are expected to cause global fossil-fuel use and resulting GHG emissions to grow substantially. During the last decade (2010 through 2019), average annual anthropogenic CO<sub>2</sub> emissions reached the highest levels in human history (*high confidence*) (IPCC 2021a). Current emissions trajectory estimates from the IPCC project global atmospheric CO<sub>2</sub> concentrations between 400 ppm (SSP1-1.9) and 1,100 ppm (SSP5-8.5) by 2100, approximately two to four times preindustrial levels (IPCC 2021a). The effects of the CO<sub>2</sub> emissions that have accumulated in the atmosphere prior to 2100 will persist well beyond 2100. If emissions from both developed and developing countries are not reduced dramatically in the coming decades, this elevation in atmospheric CO<sub>2</sub> concentrations is likely to persist for many centuries, with the potential for temperature anomalies continuing much longer (IPCC 2021a).

### **E.3.1 Climate Change Attributes**

The climate change attributes of temperature, sea-level rise, precipitation, and ocean pH provide evidence of rapid climate change.

#### **E.3.1.1 Temperature**

Climate change is evidenced, in part, by increases in surface temperatures over time. The sections that follow discuss ERF, average temperatures, and extreme temperatures as they relate to climate change.

#### **Effective Radiative Forcing**

ERF describes the magnitude of change in energy fluxes caused by a specific driver—in this case, anthropogenic GHGs—that can alter the Earth’s energy budget. Positive ERF leads to warming while negative ERF leads to cooling (IPCC 2021a). GHGs have a positive ERF. Total anthropogenic ERF has increased by 2.72 watts per square meter (W/m<sup>2</sup>) (1.96 to 3.48 W/m<sup>2</sup>) since preindustrial times and is responsible for the observed warming (IPCC 2021b). This estimate is a 0.43 W/m<sup>2</sup> increase from the IPCC’s previous report (IPCC 2013a) due to an increase in the GHG ERF. The ERF from increased atmospheric CO<sub>2</sub> concentration alone (from 1750 to 2019) is estimated to be 2.16 W/m<sup>2</sup> (plus or minus 0.26 W/m<sup>2</sup>) (IPCC 2021a). Most recently, the net heat uptake rate has been shown to be increasing. From mid-2005 to mid-2019, ERF estimates from both in situ and satellite observations were shown to be 0.77 W/m<sup>2</sup> (plus or minus 0.06 W/m<sup>2</sup>) due to an increase in absorbed solar radiation associated with decreased reflection by clouds and sea ice and a decrease in outgoing longwave radiation due to increases in trace gases and water vapor (Loeb et al. 2021). Future projections of ERF are captured in the SSPs used to model future climate conditions. SSP1-1.9, SSP1-2.6, SSP2-4.5, SSP3-7.0, and SSP5-8.5 are named according to the amount of change in ERF in 2100 relative to preindustrial conditions (i.e., prior to 1750): +1.9, +2.6, +4.5, +7.0, and +8.5 W/m<sup>2</sup>. This naming convention is a continuation from the IPCC AR5, where the RCPs were named RCP2.6, RCP4.5, RCP6.0, and RCP8.5 W/m<sup>2</sup> to denote ERF changes (GCRP 2017).

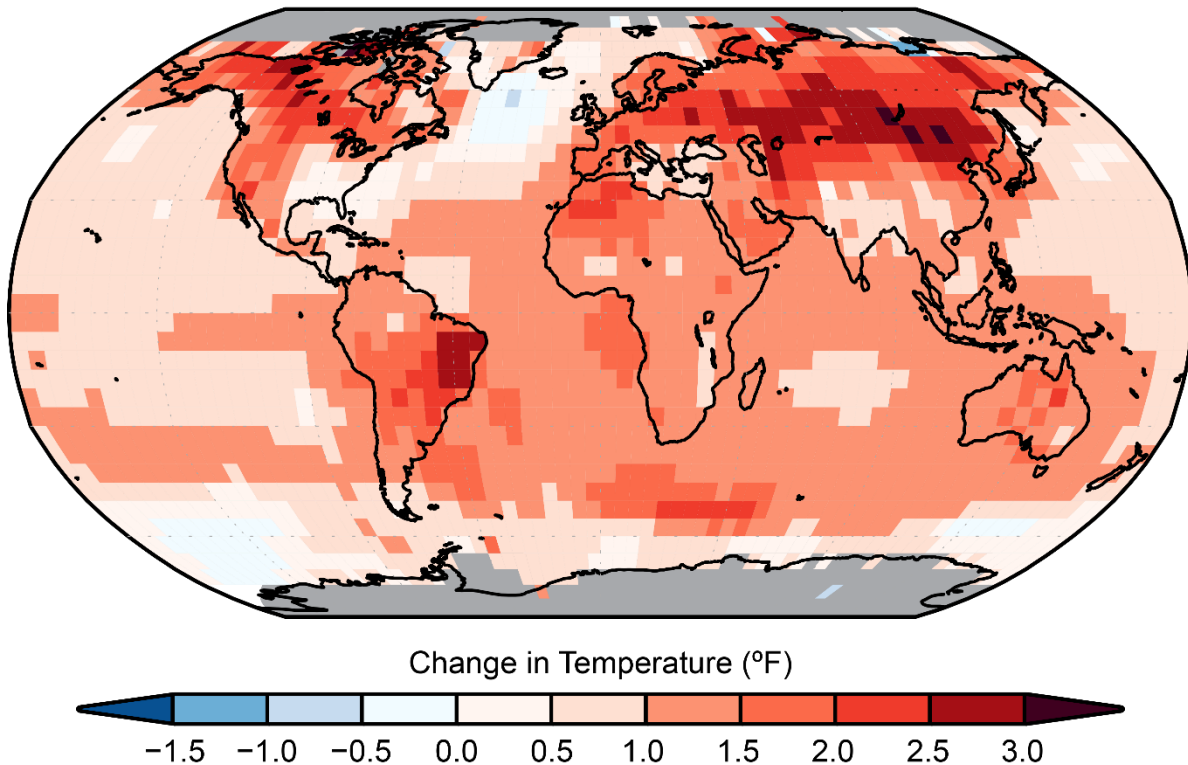

#### **Average Temperatures**

Annual average surface temperatures have increased across much of the globe in recent decades with “sixteen of the last 17 years” being “the warmest ever recorded by human observations” (GCRP 2017) (Figure E.3.1-1). Global surface temperature increased by 0.99 degree Celsius (°C) (0.84 °C to 1.10°C) from 1850–1900 to 2001–2020 and is projected to continue increasing until at least mid-century under all emissions scenarios considered (IPCC 2021a). 2022 was the 46th consecutive year (since 1977) to experience global temperatures above the 20th-century average (NOAA 2023b). Moreover, the 10 warmest years on record have all occurred since 2010 (NOAA 2023b). IPCC (2021b) has also concluded

that global surface temperatures have increased faster since 1970 than in any other 50-year period over at least the last 2,000 years (*high confidence*).

IPCC projects continued increases in global mean surface temperature over the course of this century with global average surface temperature in 2081 through 2100 *very likely* to be 1.0 to 1.8°C (1.8 to 3.2 degrees Fahrenheit [°F]) warmer<sup>14</sup> under a low GHG emissions scenario (SSP1-1.9), 2.1 to 3.5°C (3.8 to 6.3°F) warmer under an intermediate GHG emissions scenario (SSP2-4.5), and 3.3 to 5.7°C (5.9 to 10.3°F) warmer under a very high GHG emissions scenario (SSP5-8.5) (IPCC 2021b). For further information on observed and projected global average temperature trends, see IPCC 2021a and GCRP 2021a.

**Figure E.3.1-1. Global Surface Temperature Anomalies in Degrees Fahrenheit from 1986 to 2015 Relative to 1901 to 1960**

Source: GCRP 2017  
°F = degrees Fahrenheit

Surface temperatures are not rising uniformly around the globe. Warming has been particularly pronounced in the Arctic (GCRP 2017). The average Arctic temperature has increased at almost twice the global average rate over at least the past several decades (GCRP 2017). Similar to the global trend, the U.S. average temperature is about 1.0°C (1.8°F) warmer than it was in 1895, and this rate of warming is increasing—most of the warming has occurred since 1970 (GCRP 2017) (Figure E.3.1-2). Some areas of the southeast region of the United States have experienced “warming holes,” as indicated by 20th-century temperature observations, suggesting minor to no warming trends since 1901 (GCRP 2017).

<sup>14</sup> This temperature increase is compared to 1850 through 1900 global average temperature values.

**Figure E.3.1-2. Annual Global Average Surface Temperature Increases of About 0.9°C (1.6°F) from 1880 to 2021**

Source: GCRP 2021a  
°F = degrees Fahrenheit

The oceans have a large heat capacity and have been absorbing more than 90 percent of warming caused by anthropogenic GHG emissions (GCRP 2017). Due to Earth’s thermal inertia—whereby oceans absorb and dissipate heat to the atmosphere over a long period of time—warming could continue for centuries, even after atmospheric CO<sub>2</sub> is stabilized or reduced.

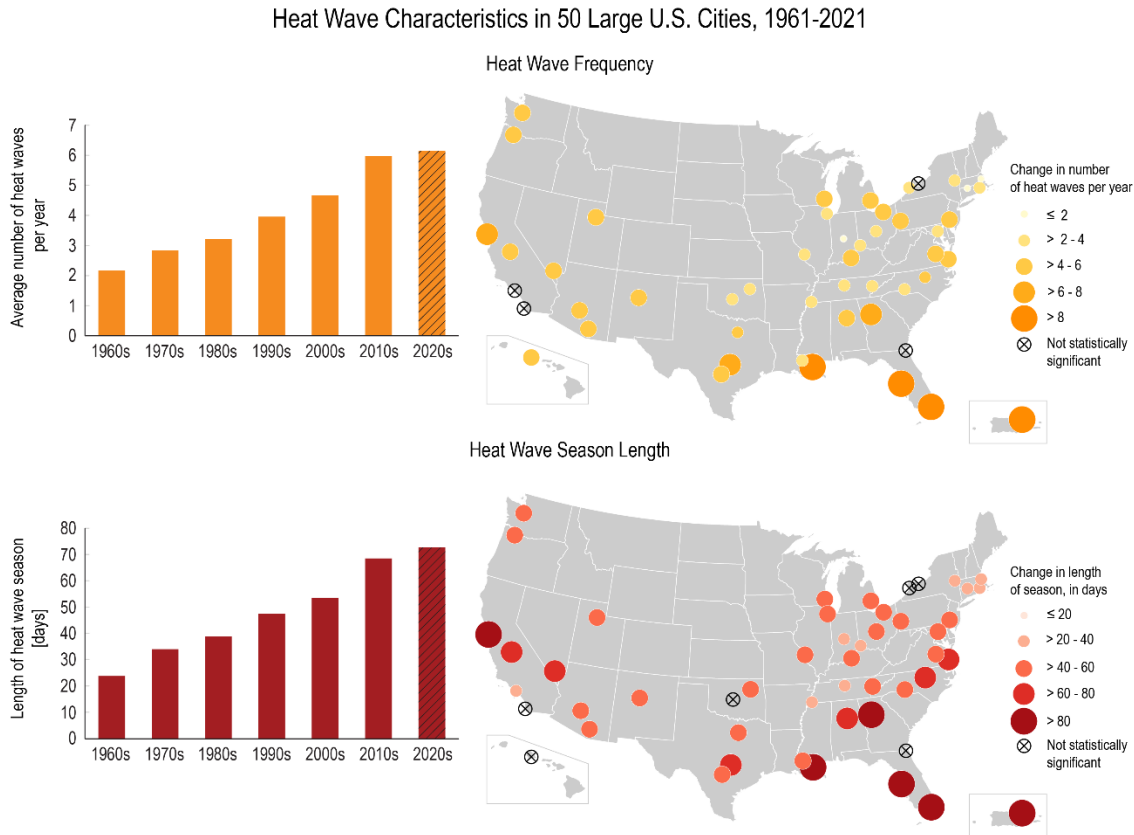

Multiple lines of evidence have recorded increasing average temperatures, including measurements from weather balloons and, more recently, satellites (GCRP 2017). In addition, higher temperatures have been independently confirmed by other global observations. For example, scientists have documented shifts to higher latitudes and elevations of certain flora and fauna habitat (GCRP 2017). The average length of the growing season has increased across the contiguous United States since the early 20th century, particularly in the northern latitudes (GCRP 2018a), and plant flowering and animal spring migrations and breeding patterns are occurring earlier on average, with exceptions in some regions (EPA 2009; GCRP 2018a; IPCC 2022a). In the United States, the length of the growing season has increased across all seven of the contiguous U.S. regions used in the GCRP (2017), although with important variability at smaller scales, with ranges from decreases of a few days to increases of 1 to 2 weeks (GCRP 2017).

### **Extreme Temperatures**

In many regions, extreme temperatures have changed substantially both in frequency and intensity since about 1950 (GCRP 2017). The IPCC concluded it is *virtually certain* that there will be more hot and fewer cold temperature extremes with increases in the frequency, duration, and magnitude of hot extremes along with heat stress; however, occasional cold winter extremes will continue to occur (IPCC 2021a). Hot days, hot nights, and heat waves have become more frequent; cold days, cold nights, and frost have become less frequent (Figure E.3.1-3) (EPA 2009; GCRP 2017; IPCC 2021a). Since 1950, the frequency of heat waves in the United States has increased, although in many regions the heat waves

recorded in the 1930s remain the most severe on record (GCRP 2017). Recent heat waves in the United States have been significant, and recent modeling shows that anthropogenic climate change is projected to dominate heat wave occurrence in the western United States and Great Lakes regions as early as this decade (Lopez et al. 2018).

Figure E.3.1-3. Heat Waves Increasing in Frequency and Duration from 1961 to 2021

Source: GCRP 2021b

Additionally, fewer unusually cold days occurred in the past few decades. The number of extreme cold waves peaked in the 1980s and reached a record low in the 2000s, with records dating back to at least 1895 (coincident with the expansion of the instrumental record) (GCRP 2017). Long-term warming driven by anthropogenic GHG emissions increases the likelihood of extreme temperatures and record warmth (Knutson et al. 2018; Meehl et al. 2016; Vogel et al. 2019a). According to IPCC, it is now considered *very likely* that humans have contributed to greater extreme heat events since the middle of the 20th century, with higher temperature changes increasing the probability of extreme heat events in some regions (IPCC 2021a). For example, the likelihood of consecutive years with record-breaking annual average temperatures from 2014 to 2016 was negligible (less than 0.03 percent) in the absence of human influence (Mann et al. 2017). Additionally, the 2017 heatwave in southern Europe was found to be at least three times more likely today than it was in 1950 due to anthropogenic climate change (Kew et al. 2018). Recent literature continues to support and strengthen such findings, projecting both geographic and temporal increases in extreme heat by the late century (Dahl et al. 2019). These projections result from the general warming trend, rather than a specific global emissions scenario or timeframe.

### E.3.1.2 Sea-Level Rise

Global temperature increases contribute to sea-level rise. The sections that follow discuss contributions to sea-level rise, observed global sea-level rise, and observed regional sea-level rise, respectively.

#### **Contributions to Sea-Level Rise**

Higher temperatures cause global sea level to rise due to both thermal expansion of ocean water and an increased transfer of water from glaciers and ice sheets to the ocean. Since the early 1970s, the majority of observed sea-level rise has come from these sources. Other factors, such as changing ocean currents and vertical land adjustments, also affect local sea-level rise. IPCC concludes that it is *very likely* that human contributions to sea-level rise are substantial (IPCC 2021a).

At the ocean surface, temperature has, on average, increased by 0.88°C (1.58°F) (0.68 to 1.01°C [1.22 to 1.82°F]) (over the reference period 1850 through 1900 compared to the 2011 through 2020 reference period) with approximately 68 percent of this warming (0.6°C [1.08°F]) having occurred since 1980 (IPCC 2021a). The ocean heat content has increased since at least 1970 (earliest reliable observations) and it is *virtually certain* that heat content will continue to rise over the 21st century, likely continuing until at least 2300, regardless of emissions scenario (IPCC 2021a). Rising ocean heat content leads to thermal heat expansion which contributes, in part, to sea-level rise.

IPCC concludes that mountain glaciers, ice caps, and snow cover have declined on average, further contributing to sea-level rise. Losses from the Greenland and Antarctic ice sheets from 1992 to 2020 have contributed to 13.5 millimeters (0.5 inch) and 7.4 millimeters (0.3 inch) of global mean sea-level rise, respectively (IPCC 2021a). Dynamic ice loss (i.e., the transfer of ice from land-based ice sheets to the ocean, which can accelerate following the collapse of supporting ice shelves) explains at least half of the Antarctic and Greenland net mass loss, with the other half coming from melting (IPCC 2021a). Although most of the last century's (1901 through 2018) global mean sea-level rise was caused by ocean thermal expansion (38 percent) and loss from glaciers (41 percent), the contribution of ice mass loss from the Greenland and Antarctic ice sheets increased and accounted for approximately 35 percent of observed global mean sea-level rise between 2006 and 2018 (IPCC 2021a).

These contributions to sea-level rise are expected to continue throughout this century. According to the IPCC, ocean warming is projected to continue throughout the 21st century (IPCC 2021b). Projections for sustained warming between 2 and 3°C (3.6 and 5.4°F) result in approximately 50 to 60 percent loss of glacier mass outside Antarctica, and approximately 60 to 75 percent loss for sustained warming between 3 and 5°C (5.4 and 9.0°F).

Under all SSP scenarios, both the Greenland ice sheet (*virtually certain*) and Antarctic ice sheet (*likely*) will continue to lose ice mass, further contributing to global mean sea-level rise. While the Greenland ice sheet is currently contributing more to global sea-level rise, Antarctica could become the larger contributor by the end of the century due to rapid retreat of ice stream and glaciers draining the ice sheet (IPCC 2021a). Recent modeling indicates that the Antarctic ice sheet contribution to sea-level rise will continue at about the current rate if Paris Agreement targets are reached (i.e., limiting warming to 2°C [3.6°F] or less). However, warming of 3°C (5.4°F) consistent with current policies has the potential to increase the contribution of Antarctic ice loss to sea-level rise to about 0.5 centimeter (0.2 inch) per year from 2060 to 2100, roughly 10 times faster than current rates (DeConto et al. 2021). New projections also show that limiting global warming to 1.5°C (2.7°F) above preindustrial levels could halve land ice contribution to sea-level rise during the 21st century, resulting in median land ice contributions to sea-

level rise ranging from 13 to 42 centimeters (5.1 to 16.5 inches) by 2100, with the higher projection due to rapid mass loss from the Antarctic ice sheet (Edwards et al. 2021).

Warming ocean temperatures affect ice sheet stability through submarine melting and altering the dynamics of ice shelves, ice streams, and glaciers. The interconnectedness of the ocean and cryosphere (e.g., glaciers and ice streams that drain the Greenland and Antarctic ice sheets into the ocean) can lead to compounding impacts, whereby ocean warming triggers dramatic ice sheet instability through enhanced melting and calving at glacier and ice stream fronts. In turn, the nonlinear relationship between ocean warming and ice mass loss could be a large driver of future global sea-level rise (IPCC 2019a).

### **Global Sea-Level Rise**

Global mean sea level rose faster in the 20th century than in any prior century over the last three millennia (IPCC 2021a). The rate of increase has been accelerating since the 1960s, with an average rate of 2.3 millimeters (0.09 inch) per year between 1971 and 2018, and an average rate of 3.7 millimeters (0.15 inch) per year between 2006 and 2018 (IPCC 2021a). Global mean sea level rose by about 1.0 to 1.7 millimeters (0.04 to 0.07 inch) per year from 1901 to 1990, a total of 11 to 14 centimeters (4 to 5 inches) (GCRP 2017). After 1993, global mean sea level rose at a faster rate of about 3 millimeters (0.12 inch) per year (GCRP 2017). Consequently, global mean sea level has risen by about 7 centimeters (3 inches) since 1990, and by 16 to 21 centimeters (7 to 8 inches) since 1900 (GCRP 2017). Relative to 1995 through 2014, global mean sea level will likely rise by 0.38 meter (1.25 feet) (0.28 to 0.55 meter [0.92 to 1.8 feet]) under SSP1-1.9 and by 0.77 meter (2.3 feet) (0.63 to 1.02 meters [2.07 to 3.35 feet]) under SSP5-8.5 by 2100; these projections are made with *medium confidence* because the uncertainty in ice sheet stability during the 21st century may alter these projections (IPCC 2021a). There is *high confidence* that global mean sea level will continue to rise for centuries past 2100 and remain elevated for thousands of years due to continuing deep ocean heat uptake and committed mass loss from the Greenland and Antarctic ice sheets (IPCC 2021a).

In addition, other studies that consider dynamic mass loss from major ice sheets indicate that sea-level rise could be even greater (Figure E.3.1-4) (Robel et al. 2019; Bamber et al. 2019). Most of these studies project a higher sea-level rise than the IPCC studies. NOAA's *Global and Regional Sea Level Rise Scenarios for the United States* estimates that global mean sea level will rise 0.3 meter (1 foot) to 2.0 meters (6.6 feet) by 2100 and 0.4 meter (1.3 feet) to 3.7 meters (12 feet) by 2150 (Sweet et al. 2022). Increasing anthropogenic GHG emissions would increase the risks posed by greater warming and sea-level rise (IPCC 2022a). Records of paleo sea level indicate that, when global mean temperatures was 2.5 to 4°C (4.5 to 7.2°F) above 1850 through 1900 levels, global mean sea level was 5 to 25 meters (16.4 to 82.0 feet) higher than current levels (IPCC 2021a).

Figure E.3.1-4. Possible Pathways for Future Sea-Level Rise (2000–2100)

Source: Sweet et al. 2022

### Regional Sea-Level Rise

Sea-level rise is not uniform across the globe, primarily because dynamic ocean heights are adjusted by ocean currents and because coastline elevations change through time because of regional tectonics, subsidence, and isostatic rebound. Throughout the period 1993 to 2018, sea levels rose fastest in the Western Pacific and slowest in the Eastern Pacific (IPCC 2021a). It is *very likely* that regional mean relative sea-level rise will continue throughout the 21st century, with variations, where a few regions that have substantial geologic land uplift rates are projected to show a deceleration in sea-level rise (IPCC 2021a).

Nationally, relative sea level has been rising at a rate of 1.1 to 2.0 inches per decade along most of the Atlantic and Gulf coasts and more than 3 inches per decade along portions of the Louisiana and Texas coasts (where land subsidence is relatively rapid) (EPA 2022m; Argus et al. 2018; Sweet et al. 2017a). Sea level is falling (due to tectonic uplift) at the rate of a few inches per decade in parts of Alaska (EPA 2009, 2022m; Argus et al. 2018; Sweet et al. 2017a; National Science and Technology Council 2008). This pattern of relative sea-level rise along the U.S. coast is projected to continue throughout this century (GCRP 2017 citing Sweet et al. 2017a). Tools such as the NOAA Sea Level Rise viewer can be used to understand the impact of coastal inundation under different sea-level rise scenarios along the coastal United States.<sup>15</sup>

Sea-level rise extends the zone of impact of storm surges and waves from tropical and other storms farther inland, causing coastal erosion and other damage. Resulting shoreline erosion is well documented. Since the 1970s, half of the coastal area in Mississippi and Texas has been eroding inland by an average of 2.6 to 3.1 meters (8.5 to 10.2 feet) per year (26 to 31 meters [85 to 102 feet] per decade). In Louisiana, a full 90 percent of the shoreline has been eroding inland at an average rate of more than 12.0 meters (39.4 feet) per year (EPA 2009; Nicholls et al. 2007), with loss of coastal wetlands

<sup>15</sup> NOAA, Office for Coastal Management, DigitalCoast, Sea Level Rise Viewer, <https://coast.noaa.gov/digitalcoast/tools/slr.html>.

in the state occurring at a variable rate of 11 to 32 square miles per year from 1932 to 2016 (Couvillion et al. 2017).<sup>16</sup> As sea level continues to rise, so will the likelihood for extensive coastal erosion (GCRP 2017 citing Barnard et al. 2011, Theuerkauf and Rodriguez 2014, and Serafin and Ruggiero 2014).

### ***E.3.1.3 Hydrologic Cycle***

As the climate warms, evaporation from land and oceans increases and more moisture can be held in the atmosphere (GCRP 2017). Depending on atmospheric conditions, this evaporation causes some areas to experience increases in precipitation events, while other areas are left more susceptible to droughts (Fujita et al. 2019). Average atmospheric water vapor content has increased since at least the 1970s over land and the oceans, and in the upper troposphere, largely consistent with air temperature increases (IPCC 2021a). Because of changes in climate, including increased moisture content in the atmosphere, heavy precipitation events have increased in frequency over most land areas (IPCC 2021b; Min et al. 2011).

The sections that follow discuss global, regional, and national trends in precipitation, droughts, streamflow, and snow cover, respectively.

### ***Precipitation***

Long-term trends in global precipitation have been observed since 1901. Between 1901 and 2010, increases in precipitation have been observed in the middle and higher latitudes of both the Northern and Southern Hemispheres, specifically in northwestern and eastern parts of North America, parts of Europe and Russia, and southern South America. Drying has been observed in the Sahel region of Africa, the Mediterranean, southern Australia, and parts of Southeast Asia. Spatial and temporal variability for precipitation is high, and data are limited for some regions (IPCC 2021b).

Over the contiguous United States, the average total annual precipitation increased approximately 4 percent from 1901 to 2016. The greatest increases from 1991 to 2015 (relative to 1901 to 1960) were noted in the Midwest, the Northeast, and the Great Plains, and there were notable decreases in areas of the Southwest (GCRP 2017). Heavy precipitation events also increased in all regions except the Southwest, primarily during the last 3 to 5 decades, with more than a 40 percent increase since 1901 in the Midwest (Figure E.3.1-5) (GCRP 2017).

---

<sup>16</sup> The shoreline erosion in Louisiana is also affected by human alterations and loss of sediment supply (EPA 2009).

Figure E.3.1-5. Increased Heavy Precipitation Events from 1901 to 2016

Source: GCRP 2018b

In general, climate change is expected to reinforce global precipitation patterns. Precipitation is projected to *very likely* increase over high latitudes, the equatorial Pacific and parts of the monsoon regions, but decrease over parts of the sub-tropics and tropics under SSP5-8.5 (IPCC 2021a). It is *very likely* that mean precipitation will increase in far north regions (*high confidence*), and heavy precipitation events are projected to increase in most regions under future warming (IPCC 2022a).

### Drought

Increased dryness has been observed in many regions since the 1950s, with intense droughts caused by higher temperatures and decreased precipitation; human-induced climate change is *likely* the main driver of these changes (IPCC 2021b). However, spatial variability for dryness is high and data availability is limited in some regions from which to draw global conclusions. IPCC (2021a) projects increased evapotranspiration and decreased soil moisture, increasing dryness over the Mediterranean, southwestern North America, south Africa, southwestern South America, and southwestern Australia (*high confidence*).

Drought trends have been changing for some regions of the United States over the past 50 years (GCRP 2017). Most regions in the United States experienced decreases in drought severity and duration over the 20th century due to increasing average precipitation and the frequency of heavy precipitation events. However, the United States continues to experience severe drought, including in the Southwest from 1999 to 2008 (EPA 2009), Texas and California in 2011 (GCRP 2017), the Midwest in 2012 (GCRP 2017), California in 2014 and 2015 (U.S. Geological Survey 2015), and the western United States from 2020 to 2022 (NOAA 2023c), which has produced drought conditions in California not seen since 1977

(Carlowicz 2021). According to tree ring data, drought conditions in the western United States over the last decade could represent the driest conditions in 500 years (GCRP 2017).

By the end of the 21st century, a third of global land area, including regions like the Mediterranean, southern Africa, southwestern Australia, southwestern South America, tropical Central America, and western Africa, are projected to suffer from at least moderate drought under high emissions scenarios (IPCC 2021a). In western North America, there is *medium confidence* that human-induced climate change has contributed to the increases in agricultural and ecological droughts, with projected reductions in soil moisture and an increase in drought severity for mean global warming of 2°C and above (IPCC 2021a). Twenty-first-century drought risk in the Southwest and central plains will likely be higher than at any time since at least 1100 Current Era (CE) under both RCP4.5 and RCP8.5, increasing the possibility of megadroughts (i.e., droughts lasting 2 decades or more) in these regions (Cook et al. 2015). A more recent study expands upon this concept, showing that the 2000 to 2018 southwestern North America drought was the second driest 19-year period since 800 CE, exceeded only by a late-1500s megadrought, noting that anthropogenic warming increases the probability of otherwise moderate droughts becoming historic megadroughts (Williams et al. 2020).

While current levels of climate change already manifest moderate risks of increased water scarcity, vegetation loss, and wildfire damage, these risks are projected to become more severe with future temperature increases (IPCC 2019b). In addition, increased warming is projected to shift climate zones poleward and increase the amount of land prone to drought (IPCC 2019b).

### **Streamflow**

Melting snow and ice, increased evaporation, and changes in precipitation patterns all affect surface water. Previous assessments indicate variable changes in streamflow and river discharge. The northwest United States has experienced long-term declines in streamflow as a result of declining winter precipitation and, more generally, the western United States has seen recent declines due to drought (GCRP 2017). In contrast, high streamflow is increasing across parts of the Midwest, Mississippi Valley, and eastern United States as a result of increases in heavy precipitation (GCRP 2017). Other assessments show even greater global variability in trends, where decreases in streamflow were observed in mainly low- and mid-latitude river basins, while increasing flow at higher latitudes could have resulted from possible permafrost thawing and increased snowmelt (IPCC 2021a). Changes in precipitation have also been identified as a major driver for changing discharge trends across regions (IPCC 2021a).

These streamflow drivers are expected to continue to change throughout the 21st century, with more frequent and intense heavy precipitation events (*high confidence*) and more precipitation falling as rain rather than snow, thereby decreasing snowpack and snowmelt (*high confidence*) in the United States (GCRP 2017). Changes in streamflow are also dominated by snowpack and glacier-fed mountain basins, which are projected to decline and produce earlier spring peak flows (IPCC 2019a).

### **Snow Cover**

Across the Northern Hemisphere, snow cover extent (in June) decreased by approximately 11 percent per decade over the 1967 to 2012 period (IPCC 2021b citing Vaughan et al. 2013) with future snow cover extent and duration projected to continue to decrease as global climate warms (IPCC 2021a). Changes in air temperature, decreased surface albedo, and increased atmospheric water vapor drove a downward trend in maximum snow cover per decade from 1961 to 2015 across North America (GCRP

2017). The amount of snow at the end of the winter season, which is important for water supply provided by snowmelt, has decreased because of springtime warming (GCRP 2017). In addition, North America, Europe, South Asia, and East Asia have experienced a decreasing number of snowfall events; according to IPCC, this is *likely* due to increasing winter temperatures (IPCC 2021a).

Recent studies support these findings, and project that spring snow cover could decrease by as much as 35 percent relative to 1986 to 2005 by the end of the century under RCP8.5 (IPCC 2019a). Furthermore, the most recent IPCC projections show that Northern Hemisphere spring snow cover extent could decrease by about 8 percent per 1°C (1.8°F) of global surface air temperature increase in the future (IPCC 2021a).

#### **E.3.1.4 Ocean pH**

With higher atmospheric CO<sub>2</sub> concentrations in recent decades, oceans have absorbed more CO<sub>2</sub>, which lowers the potential of hydrogen (pH)—or increases the acidity—of the water. When CO<sub>2</sub> dissolves in seawater, the hydrogen ion concentration of the water increases; this is measured as a decrease in pH. Compared to the preindustrial period, the pH of the world’s oceans has decreased by 0.1 unit (IPCC 2021a). Because pH is measured on a logarithmic scale, this decrease represents about a 30 percent increase in the hydrogen ion concentration of seawater, a substantial acidification of the oceans. Although research on the ultimate impacts of declining ocean pH is limited, available observational, laboratory, and theoretical studies indicate that acidification could interfere with the calcification of coral reefs and inhibit the growth and survival of coral reef ecosystems (EPA 2009; GCRP 2017; IPCC 2021a). The Fourth National Climate Assessment (NCA4)<sup>17</sup> notes that, by 2100 under the RCP8.5 emissions scenario, nearly all coral reefs are projected to be surrounded by acidified seawater that will challenge coral growth (GCRP 2017, GCRP 2018a citing Ricke et al. 2013). Under lower emissions scenarios such as RCP4.5, ecological impacts on coral reefs are reduced but not avoided (GCRP 2018a). If global temperatures reach an average increase of 1.5°C (2.7°F), 70 to 90 percent of coral reefs are projected to decline, with even greater losses at 2°C (3.6°F) (IPCC 2021a). At 2°C (3.6°F) above preindustrial levels, mass mortalities of coral reefs are *virtually certain* (IPCC 2021a).

The global average surface ocean acidity is projected to increase in acidity (decrease in pH) by 100 to 150 percent by the end of the century under RCP8.5 relative to historical conditions (*high confidence*) (GCRP 2017). Most recent IPCC (2021a) projections indicate a decreasing ocean surface pH under all scenarios (except SSP1-1.9 and SSP1-2.6), with a 0.44-unit decrease under SSP5-8.5 (a 175 percent increase in the hydrogen ion concentration of seawater) by the end of the century (1870 to 1899 compared to 2080 to 2099 values).

### **E.3.2 Increased Incidence of Severe Weather Events**

Tropical cyclones appear to be increasing in intensity since 1970, but no clear trend in the frequency of tropical cyclones each year has been observed. Identifying long-term trends of tropical cyclones has been difficult because observations were limited prior to the satellite era (IPCC 2021a). However, there is observational evidence of an increase in intense tropical cyclone activity correlated with increases of sea-surface temperatures in the North Atlantic, which includes the Gulf Stream, since about 1970 (GCRP 2017). The tracks of tropical cyclones have shifted in a warming climate, migrating toward the poles

---

<sup>17</sup> Development of the GCRP’s Fifth National Climate Assessment (NCA5) is currently underway. The draft report is available and final publication is anticipated in late 2023. Findings from NCA5 will be included in the Final EIS if the final report becomes available in time.

(GCRP 2017). According to IPCC, while recent assessments show no trend in the frequency of U.S. landfall events this past century, an increasing trend in intensity since the 1970s is *virtually certain* (IPCC 2021a). Additionally, recent projections indicate that climate change could increase the frequency of the most intense tropical cyclones by the end of the century, but it is still unclear how the overall frequency of events might change (GCRP 2017). This trend has been substantiated by the IPCC (2021a), which shows that globally, major tropical cyclone intensities (Category 3 and above) have increased over the past 4 decades. Thus overall, IPCC (2021a) projects tropical cyclones to increase in intensity despite a decrease in frequency in most tropical regions (*medium confidence*).

Climate change also causes hurricanes and tropical cyclones to produce heavier precipitation, in part because a warmer atmosphere holds more moisture and increases the energy available for convection, causing stronger storms and heavier precipitation (GCRP 2017; Gertler and O’Gorman 2019). Globally, the frequency and intensity of heavy precipitation events has increased (*high confidence*) in a majority of land regions, particularly in North America, Europe, and Asia (IPCC 2021a). IPCC (2021a) states that with increasing temperatures, it is *virtually certain* that heavy precipitation events (including those from tropical cyclones) will become more frequent and intense over all continents.

The influence of climate change on recent storms is well documented. For example, the rainfall produced in Texas and Louisiana by Hurricane Harvey in 2014 was increased by about 15 to 19 percent due to climate change (Risser and Wehner 2017; van Oldenborgh et al. 2017). Climate change also could increase the probability of a similar extreme event by 17 percent through 2100 relative to the period from 1981 to 2000 under RCP8.5 (Emanuel 2017). Looking forward, tropical cyclone rainfall amounts in the eastern United States could increase by 8 to 17 percent relative to the time period between 1980 and 2006 as a result of a warmer climate (Wright et al. 2015). The frequency of weather and climate disasters (including those causing more than \$1 billion in damages) has increased in the United States (GCRP 2018a).

There is *low confidence* in historical trends of hail and severe thunderstorms (IPCC 2021a), which makes their relationship to climate change difficult to resolve. While IPCC states that climate models consistently project environmental changes that would support an increase in the frequency and intensity of severe thunderstorms that combine tornadoes, hail, and winds, there is *low confidence* in the details of the projected increases. Similarly, GCRP (2017) also indicates *low confidence* for future projections of severe thunderstorms including tornadoes, hail, and extreme winds.

Changes in ocean heat content and freshwater-driven buoyancy as a result of climate change could potentially weaken the Atlantic meridional overturning circulation (AMOC), a mechanism for heat transport in the North Atlantic Ocean that could drive dramatic changes to the regional climates of North America and Europe. However, there is currently *low confidence* in models that show AMOC weakening over the 21st century under a high emissions scenario (RCP8.5) (GCRP 2017). Models show low agreement in 20th-century AMOC trends (IPCC 2021a). Recent observations show a decline in AMOC since the 2000s; however, this cannot be distinguished from internal variability (IPCC 2021a).

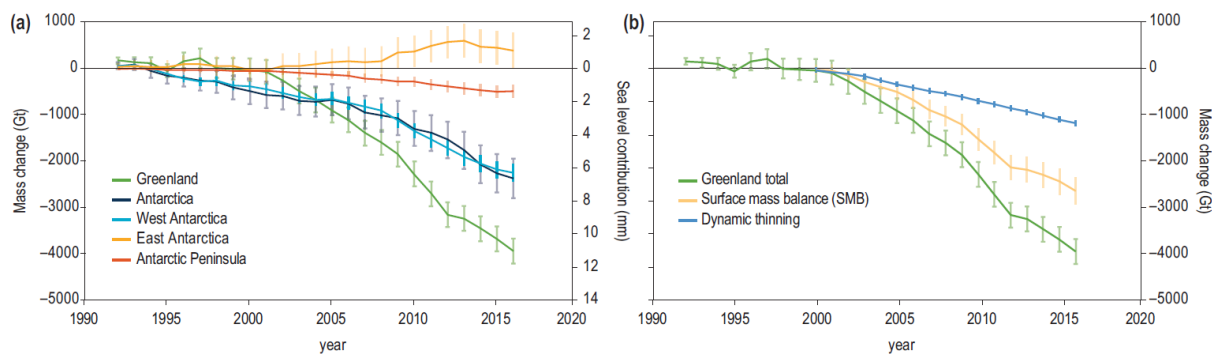

Climate change is also driving increased wildfire activity. The number of large wildfires in the western United States increased from 1984 to 2011, and area burned by wildfire has been increasing since the 1970s (GCRP 2017). These changes are driven, in part, by changes in climate, such as increasing temperatures, more intense droughts, reduced snowpack, and increased fuel availability and flammability (GCRP 2017, 2018a). Observations of wildfires in western U.S. forests indicate that the area burned by wildfire from 1984 to 2015 was twice what would be expected in the absence of climate change (Abatzoglou and Williams 2016).

Wildfires are projected to further increase in intensity, duration, and frequency under climate change. Projections indicate that for the western United States, large fires will become more of an annual occurrence and very large fires (larger than 50,000 acres) will increase by 2050 under both low and high emissions scenarios (RCP4.5 and RCP8.5) (GCRP 2017). The southeast is also expected to see an increase in wildfires, though with substantial differences between ecoregions (Prestemon et al. 2016). Similarly, Alaska is expected to experience a longer fire season, with a higher risk of severe fires and greater total area burned (GCRP 2017). Wildfires are complex systems, but modeling focused on the climate variables that are closely linked to fire risk (e.g., surface temperature, snowmelt timing) is quite robust and shows that conditions conducive to wildfires are expected to continue under climate change (GCRP 2017).

### E.3.3 Changes in Ice Cover and Permafrost

Changes in air and ocean temperatures, precipitation onto the ice mass, and water salinity are affecting glaciers, sea-ice cover, and ice sheets. Numerous studies have confirmed that glaciers and ice sheets have shrunk substantially in the past half century. Satellite images have documented mass loss from the Greenland ice sheet and the West Antarctic ice sheet (IPCC 2021a; GCRP 2017). Figure E.3.3-1 shows polar ice sheet mass change from 1992 to 2016.

Figure E.3.3-1. Cumulative Ice Sheet Mass Change from 1992 to 2016

Notes:

Panel (a) shows cumulative mass change and corresponding sea-level rise contributions for different ice sheet regions. Panel (b) shows Greenland ice sheet mass change components from surface mass balance (orange) and dynamic thinning (blue) for 2000 to 2016. Uncertainties bars are 1 standard deviation.

Source: IPCC 2019a

Gt = gigaton

Average Arctic sea-ice area in August, September, and October has decreased approximately 25 percent in the past 40 years (1979–1988 to 2010–2019) and has decreased to some extent in every month of the year (IPCC 2021a). Warming in the Arctic has proceeded at about twice the rate as the global average, leading to decreases in summer sea-ice extent, glacier and ice sheet mass loss, coastal erosion, and permafrost thawing (IPCC 2021a).<sup>18</sup> Some Arctic ice that previously was thick enough to last through summer has now thinned enough to melt completely in summer. As of 2020, the 12 lowest Arctic sea-ice extents in the satellite era occurred in the last 12 years (Kumar et al. 2020a). It is *very likely* that more than half of the observed Arctic sea-ice loss in summer is due to anthropogenic climate change (IPCC 2021a).

<sup>18</sup> Permafrost thawing releases CO<sub>2</sub> and CH<sub>4</sub> into the atmosphere.

In March 2016, the Arctic experienced the lowest winter maximum ice extent in the satellite record (1979 to 2016), 7 percent below the 1981 to 2010 average (Perovich et al. 2016). Multiyear ice (more than 1 year old) and first-year ice were 22 percent and 78 percent of the ice cover, respectively, compared to 45 percent and 55 percent in 1985 (Perovich et al. 2016). In September 2016, the Arctic sea-ice minimum extent was 33 percent lower than the 1981 to 2010 average minimum ice extent, 22 percent larger than the record minimum set in 2012, and tied with 2007 for the second lowest value in the satellite record (1979 to 2016) (Perovich et al. 2016).

As of 2021, the Arctic experienced the 15 lowest summer minimum ice extents (occurring in September), all within the last 15 years (Meier et al. 2021). By end of summer in 2021, multiyear ice reached its second lowest level since 1985, based on available data (Meier et al. 2021).

There is *very high confidence* that Arctic sea ice volume and thickness have decreased in the period after 1979. However, there is *low confidence* in the quantitative volume and thickness estimates due to poor observations; current analyses show an approximately 72 percent reduction between 1979 and 2016 (IPCC 2021a). These area and thickness reductions allow winds to generate stronger waves, which have increased shoreline erosion along the Alaskan coast. Alaska has also experienced increased thawing of the permafrost base of up to 1.6 inches per year since 1992 (EPA 2009; National Science and Technology Council 2008).

There is *high confidence* that permafrost temperatures have been increasing over the past 3 to 4 decades in the permafrost regions (IPCC 2021a). Globally, permafrost has warmed approximately 0.29°C (0.52°F) between 2007 and 2016. The active layer thickness of the permafrost (a layer subject to annual temperature changes) has increased across the entire Arctic region (IPCC 2021a). At lower depths, IPCC (2019a) stated with *very high confidence* that record high permafrost temperatures at the depth of the zero annual amplitude (the depth about 10 to 20 meters [32.8 to 65.6 feet] below the surface where the seasonal soil temperature cycle vanishes) were observed in recent decades in the northern circumpolar permafrost region. They also conclude (*high confidence*) that global warming over the last decades has led to widespread permafrost warming. Complete permafrost thaw in recent decades is a common phenomenon across the permafrost regions (IPCC 2021a). Continued thawing of permafrost over the next century is *virtually certain*, with projections showing the volume of perennially frozen soil within the upper 3 meters (9.8 feet) of the ground decreasing by about 25 percent per 1°C (1.8°F) of global surface air temperature increase (IPCC 2021a).

The loss of Arctic sea ice is projected to continue throughout the 21st century and could *very likely* result in nearly sea-ice-free<sup>19</sup> late summers in the Arctic Ocean by the 2040s (*very high confidence*) (GCRP 2017). IPCC (2021a) shows that the Arctic Ocean will *likely* become practically sea-ice free during the seasonal sea-ice minimum for the first time before 2050 regardless of SSP scenario. At the same time, permafrost is projected to continue to decrease, with a switch from continuous to discontinuous permafrost expected over the 21st century (GCRP 2017 citing Vaughan et al. 2013, Grosse et al. 2016, and Schuur et al. 2015). Projections show that by the end of the century, near-surface (i.e., within 3 to 4 meters) permafrost could decrease by approximately 24 to 69 percent relative to the 1986 to 2005 baseline time period, based on RCP2.6 and RCP8.5, respectively (IPCC 2019a) and it is *virtually certain* that permafrost extent and volume will shrink as the climate warms (IPCC 2021a).

---

<sup>19</sup> *Sea-ice free* means sea-ice area below 1 million square kilometers (386,102 square miles).

## E.4 Analysis Methods

NHTSA provides an overview of the methods used to characterize the effects of the alternatives on climate in Chapter 5, Section 5.3, *Analysis Methods*. Additional detail is provided below.

### E.4.1 Uncertainty in Climate Modeling

The methods used to characterize emissions and climate impacts consider multiple sources of uncertainty. Sources of uncertainty include the following, in addition to many other factors.

- The pace and effects of technology changes in the transportation sector and other sectors that emit GHGs.
- Changes in the future fuel supply and fuel characteristics that could affect emissions.
- Sensitivity of climate to increased GHG concentrations.
- The rate of change in the climate system in response to changing GHG concentrations.
- Potential existence of thresholds in the climate system (which cannot be predicted or simulated).
- Regional differences in the magnitude and rate of climate change.
- Sensitivity to natural variability, such as El Niño conditions.

Moss and Schneider (2000) characterize the “cascade of uncertainty” in climate change simulations (Figure E.4.1-1). As indicated in Figure E.4.1-1, the emissions estimates used in this EIS have narrower bands of uncertainty than global climate sensitivity, which is less uncertain than regional climate change impacts. The impacts on climate are, in turn, less uncertain than the impacts of climate change on affected resources (such as terrestrial and coastal ecosystems, human health, and other resources discussed in Section E.5, *Health, Societal, and Environmental Impacts of Climate Change*). Although the uncertainty bands broaden with each successive step in the analytic chain, not all values within the bands are equally likely; the mid-range values have the highest likelihood.

**Figure E.4.1-1. Cascade of Uncertainty in Climate Change Simulations**

Source: Moss and Schneider 2000

Scientific understanding of the climate system is incomplete; like any analysis of complex, long-term changes to support decision-making, evaluating reasonably foreseeable impacts on the human environment involves many assumptions and uncertainties. This EIS uses methods and data to analyze climate impacts that represent the best and most current information available on this topic and that have been subjected to extensive peer review and scrutiny. The information cited throughout this section, extracted from the most recent EPA, IPCC, and GCRP reports on climate change, has endured a

more thorough and systematic review process than information on virtually any other topic in environmental science and policy. The tools used to perform the climate change impacts analysis such as the Model for the Assessment of Greenhouse Gas-Induced Climate Change (MAGICC) are widely available and are commonly used in the scientific community.

The CCSP Synthesis and Assessment Product 3.1 report on the strengths and limitations of climate models (CCSP 2008) provides a thorough discussion of the methodological limitations regarding modeling. Additionally, Chapter 1 of IPCC WGI AR6 provides an evaluation of the performance of global climate models. Readers interested in a detailed treatment of this topic will find the Technical Summary and Chapter 1 of IPCC WGI AR6 useful in understanding the issues that underpin the modeling of environmental impacts of the Proposed Action and alternatives on climate change.

## **E.4.2 Methods for Modeling Greenhouse Gas Emissions**

This EIS compares GHG emissions under each action alternative to those under the No-Action Alternative for both LD passenger vehicles, HDPUVs, and the combined CAFE and HDPUV FE alternatives. GHG emissions under each alternative were estimated using the methods described in Chapter 2, Section 2.3, *Standard-Setting and EIS Methods and Assumptions*. For years 2022 through 2050, the emissions estimates in this EIS include tailpipe emissions from fuel combustion and upstream emissions from the production and distribution of fuel for LD passenger vehicles and HDPUVs. GHG emissions were estimated by the DOT Volpe National Transportation Systems Center (Volpe Center) using the CAFE Compliance and Effects Model (referred to as the CAFE Model), described in Chapter 2, Section 2.3.1, *CAFE Model*. To calculate tailpipe CO<sub>2</sub> emissions, the CAFE Model applies estimates of the density and carbon content of gasoline and other fuels. To calculate tailpipe CH<sub>4</sub> and N<sub>2</sub>O emissions, the CAFE Model applies gram-per-mile emissions factors Volpe Center staff referenced from EPA's Motor Vehicle Emissions Simulator (MOVES).<sup>20</sup> To calculate GHG emissions from upstream processes such as refining and electricity generation, the CAFE Model applies process-specific emissions factors specified on a gram-per-British thermal unit (Btu) basis; Volpe Center staff developed these emissions factors using the Greenhouse Gases and Regulated Emissions in Transportation (GREET) model, developed by the DOE Argonne National Laboratory.

For the climate analysis, GHG emissions trajectories are projected through the year 2100. In order to estimate GHG emissions for the LD and HD fleets for 2051 to 2100, NHTSA extrapolated from the aforementioned CAFE Model results by applying the projected rate of change in U.S. transportation fuel consumption over this period from the global climate scenario (SSP2-4.5) used in the analysis.<sup>21,22</sup> For 2051 through 2100, the SSP2-4.5 and SSP3-7.0 scenarios project that U.S. road transportation fuel consumption will decline slightly because of assumed improvements in efficiency of internal combustion engine (ICE)-powered vehicles and increased deployment of non-ICE vehicles with higher drivetrain efficiencies. However, the projection of road transport fuel consumption beyond 2050 does not change substantially. Therefore, emissions remain relatively constant from 2050 through 2100.<sup>23</sup> The

---

<sup>20</sup> All downstream emissions estimates in the CAFE Model use emissions factors from EPA's MOVES3 model version (EPA 2022a).

<sup>21</sup> More information regarding global emissions scenarios can be found in Section E.4.3.4, *Global Emissions Scenarios*.

<sup>22</sup> 2050 is the last year for which the CAFE Model provides estimates of fleet CO<sub>2</sub> emissions for this analysis.

<sup>23</sup> NHTSA anticipates a larger post-2050 decline in passenger car and light truck energy consumption than what is projected in the SSP3-7.0 scenario due to updated projections around technology availability and adoption, as well as other factors that

assumptions and methods used to extrapolate GHG emissions estimates beyond 2050 for this EIS are broadly consistent with those used in the *MY 2011–2015 CAFE Final EIS* (NHTSA 2008), the *MY 2012–2016 CAFE Final EIS* (NHTSA 2010), *Phase 1 Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles Final EIS* (NHTSA 2011), *MY 2017–2025 CAFE Final EIS* (NHTSA 2012), *Phase 2 Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles Final EIS* (NHTSA 2016b), the *MY 2021–2026 Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule Final EIS* (NHTSA 2020), and the *MY 2024–2026 CAFE Final EIS and SEIS* (NHTSA 2021, 2022).

The emissions estimates include global CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O emissions resulting from direct fuel combustion and the production and distribution of fuel and electricity (upstream emissions).<sup>24</sup> The MOVES model also estimated non-GHG emissions—both criteria pollutants and air toxics—which are used as inputs in MAGICC7. Criteria pollutants included are sulfur dioxide (SO<sub>2</sub>), nitrogen oxides (NO<sub>x</sub>), carbon monoxide (CO), fine particulate matter 2.5 microns or less in diameter (PM<sub>2.5</sub>), and volatile organic compounds (VOCs). Air toxics included are acetaldehyde, acrolein, benzene, 1,3-butadiene, formaldehyde, and diesel particulate matter 10 microns or less in diameter.

Fuel savings from more stringent CAFE and HDPUV FE standards would result in lower overall emissions of CO<sub>2</sub> (the main GHG emitted) because of reduced refining, distribution, and use of transportation fuels.<sup>25</sup> Fuel efficiency, fuel consumption, and CO<sub>2</sub> emissions are closely connected. Fuel efficiency describes how much fuel a vehicle requires to perform a certain amount of work (for example, how many miles it can travel or how many tons it can carry per mile traveled). A vehicle is more fuel efficient if it can perform more work while consuming less fuel. Lower fuel consumption reduces CO<sub>2</sub> emissions directly because the primary source of vehicle-related CO<sub>2</sub> emissions is the combustion of carbon-based fuel in ICEs; combustion of a hydrocarbon essentially produces energy (used to power the vehicle), CO<sub>2</sub>, and water. Therefore, lowering fuel consumption lowers CO<sub>2</sub> emissions, and greater fuel efficiency means less CO<sub>2</sub> emissions.

NHTSA estimated reductions in tailpipe CO<sub>2</sub> emissions resulting from fuel savings by assuming that the carbon content of gasoline, diesel, and other fuels is converted entirely to CO<sub>2</sub> during the combustion

---

affect fuel consumption. However, the EIS approach for projecting emissions from 2051 to 2100 is consistent with methods used in recent NHTSA EISs, conservative in terms of estimating environmental impacts, and reasonable given the uncertainty associated with post-2050 projections.

<sup>24</sup> Upstream emissions considered in this EIS include those that occur in the United States during the recovery, extraction, and transportation of crude petroleum, as well as during the refining, storage, and distribution of transportation fuels. Emissions from each of these phases of fuel supply are estimated using factors obtained from the Argonne National Laboratory GREET model. A portion of finished motor fuels are refined in the United States using imported crude petroleum as a feedstock, and GREET's emissions factors are used to estimate emissions associated with transporting imported petroleum from coastal port facilities to U.S. refineries, refining it to produce transportation fuels, and storing and distributing those fuels. GREET's emissions factors are also used to estimate domestic emissions from transportation, storage, and distribution of motor fuels that are imported to the United States in refined form.

<sup>25</sup> For this rulemaking, NHTSA estimated emissions of vehicular CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O emissions, but did not estimate vehicular emissions of HFCs. HFCs are released to the atmosphere only through air-conditioning system leakage and are not directly related to fuel efficiency. NHTSA's authority under the Energy Policy and Conservation Act, as amended by the Energy Independence and Security Act, extends only to the regulation of vehicle fuel efficiency. For reference, CH<sub>4</sub> and N<sub>2</sub>O account for 4 percent of the tailpipe GHG emissions from LD passenger vehicles and light trucks, HDPUVs, and combined tailpipe GHG emissions from all vehicle classes, respectively. CO<sub>2</sub> emissions account for the remaining 96 percent in each category. Of the total (including non-tailpipe) GHG emissions from passenger cars and light trucks, tailpipe CO<sub>2</sub> represents approximately 97.4 percent, tailpipe CH<sub>4</sub> and N<sub>2</sub>O represent approximately 0.7 percent, and HFCs represent approximately 1.9 percent (values are calculated from EPA 2023a).

process.<sup>26</sup> Specifically, NHTSA estimated CO<sub>2</sub> emissions from fuel combustion as the product of the volume of each type of fuel consumed (in gallons), its mass density (in grams per gallon), the fraction of its total mass represented by carbon (measured as a proportion), and CO<sub>2</sub> emissions per gram of fuel carbon (the ratio of the molecular weights of CO<sub>2</sub> and elemental carbon). NHTSA estimated changes in tailpipe CH<sub>4</sub> and N<sub>2</sub>O emissions by applying MOVES-based emissions factors for these GHGs to estimated annual mileage accumulation (i.e., VMT) of vehicles of different types and vintages.

Reduced fuel consumption also lowers CO<sub>2</sub> emissions that result from the use of carbon-based energy sources during fuel production and distribution. At the same time, new CAFE and HDPUV FE standards may also lead to increased CO<sub>2</sub> emissions from processes involved in producing and delivering any alternative energy sources (i.e., other than petroleum) for which consumption increases. In particular, the CAFE Model shows electricity consumption by LD vehicles increasing more rapidly under the action alternatives than under the No-Action Alternative. NHTSA estimated the CO<sub>2</sub> emissions during each phase of fuel and electricity production and distribution (upstream emissions) using CO<sub>2</sub> emissions rates obtained from the GREET model using previous assumptions about how fuel savings are reflected in reductions in activity during each phase of fuel production and distribution. For this EIS, the Argonne National Laboratory GREET model was updated from the 2021 version to the 2022 version. The total reduction in CO<sub>2</sub> emissions from improving fuel economy under each alternative is the sum of the reductions in motor vehicle emissions from reduced fuel combustion compared to the relevant No-Action Alternative plus the reduction in upstream emissions from a lower volume of fuel production and distribution than is projected under the relevant No-Action Alternative (minus the increase in upstream emissions resulting from increased electricity generation).

### **E.4.3 Methods for Estimating Climate Effects**

This EIS estimates and reports the projected reductions in GHG emissions, particularly CO<sub>2</sub>, that would result from the action alternatives for CAFE standards, HDPUV FE standards, and the combined set of alternatives. The reduction in GHG emissions is a direct effect of the increased stringency in fuel economy associated with the action alternatives. The reductions in CO<sub>2</sub> emissions, in turn, cause indirect effects on five attributes of climate change: CO<sub>2</sub> concentrations, temperature, sea level, precipitation, and ocean pH.

The subsections that follow describe methods and models used to characterize the reductions in GHG emissions and the indirect effects on the attributes of climate change. Importantly, this EIS uses the SSPs that were developed for the IPCC AR6 report to represent a range of future climate change scenarios and development pathways. Similar to RCPs, which were developed for the previous IPCC AR5 report, the SSPs utilize global socioeconomic projections to derive time-dependent global GHG concentrations and drive general circulation model simulations of climate change. The SSPs were designed to provide an expanded set of GHG concentration scenarios for the Coupled Model Intercomparison Project Phase 6 (CMIP6) based on a range of socioeconomic scenarios, with SSP1 through 5 accounting for various global mitigation and adaptation measures, described in further detail in the following subsections.

---

<sup>26</sup> This assumption results in a slight overestimate of CO<sub>2</sub> emissions because a small fraction of the carbon content of gasoline is emitted as CO and unburned hydrocarbons. However, the magnitude of this overestimation is likely to be extremely small. This approach is consistent with the recommendation of IPCC for Tier 1 national GHG emissions inventories (IPCC 2006).

### E.4.3.1 *MAGICC Modeling*

NHTSA used a reduced-complexity climate model (MAGICC) to estimate the changes in CO<sub>2</sub> concentrations and global mean surface temperature and used increases in global mean surface temperature combined with an approach and coefficients from IPCC WGI AR6 (IPCC 2021a) to estimate changes in global precipitation and sea-level rise. NHTSA used the publicly available modeling software<sup>27</sup> MAGICC7 (Meinshausen et al. 2020) to estimate changes in key direct and indirect effects. NHTSA used MAGICC7 to incorporate the estimated reductions in emissions of CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, CO, NO<sub>x</sub>, SO<sub>2</sub>, and VOCs and the associated estimated changes in upstream emissions using factors obtained from the GREET model and CAFE Model analysis. NHTSA also performed a sensitivity analysis to examine variations in the direct and indirect climate impacts of the CAFE standard and HDPUV FE standard action alternatives under different assumptions about the sensitivity of climate to GHG concentrations in Earth's atmosphere. The results of the sensitivity analysis can be used to infer how the variation in GHG emissions associated with the action alternatives affects the anticipated magnitudes of direct and indirect climate impacts.

The selection of MAGICC for this analysis was driven by several factors:

- MAGICC has been used in the peer-reviewed literature to evaluate changes in global mean surface temperature and sea-level rise. Applications include the IPCC WGI AR6 (IPCC 2021a) and IPCC WGI AR5 (IPCC 2013a), where it was used to estimate global mean surface temperature and sea-level rise for simulations of global emissions scenarios that were not run with the more complex atmospheric-ocean general circulation models (AOGCMs) (Meinshausen et al. 2011).<sup>28</sup>
- MAGICC is designed for the type of analysis performed in this EIS.
- More complex AOGCMs are not designed for the type of sensitivity analysis performed in this EIS and are best used to provide results for groups of scenarios with much greater differences in emissions.
- MAGICC7 uses updated carbon cycle models that can emulate temperature-feedback impacts on the heterotrophic respiration carbon fluxes.
- MAGICC7 incorporates the latest science from IPCC AR6 and AR5; MAGICC7 was used in the IPCC WGI AR6 (IPCC 2021a).

### E.4.3.2 *Sea-Level Rise*

NHTSA estimated the projected changes in global mean sea level based on data from the IPCC WGI AR6 (IPCC 2021a).<sup>29, 30</sup> The sea-level rise analysis uses global mean surface temperature data and projections from 1950 to 2100, and global mean sea-level rise data from 1950 to 2019 and projections from 2020 to

---

<sup>27</sup> MAGICC7, accessible for general use, is distributed under the Creative Commons Attribution-NonCommercial 4.0 International (CC BY-NC 4.0) license, which forbids commercial application. NHTSA has entered into a direct agreement with ClimateResource, the creators of MAGICC, to incorporate MAGICC7 modeling in this analysis.

<sup>28</sup> As a reduced-complexity model, MAGICC relies on a more limited number of potential climate and carbon cycle responses and a higher level of parameterization to proxy carbon cycle force than more complex models. Results from MAGICC (e.g., projected atmospheric CO<sub>2</sub> concentration in 2100) will, therefore, vary somewhat from those of more complex models (Meinshausen et al. 2011).

<sup>29</sup> Sea-level rise outputs from MAGICC7 were not used because this component of the model is still under development.

<sup>30</sup> In this EIS, the relationship between sea-level rise and global mean surface temperature developed using IPCC AR6 is used to estimate sea-level rise using global mean surface temperatures from AR6 for the SSP scenarios.

2100 under various SSP scenarios. These projections are based on the climate ensemble data of the SSP<sup>31</sup> scenarios for sea level and temperature. Simple equations relating projected changes in sea level to projected changes in temperature are developed for each scenario using a regression model.

The regression models for the all the SSP scenarios were developed directly from their respective data. For example, the regression models for SSP2-4.5 were used to estimate sea-level rise for the SSP2-4.5 scenario. The temperature outputs of the MAGICC simulations are used as input to these regression models to project sea-level rise for each SSP scenario.<sup>32</sup>

### **E.4.3.3 Ocean pH**

NHTSA projected changes in ocean pH using the CO<sub>2</sub> System Calculations (CO2SYS) model, which calculates parameters of the CO<sub>2</sub> system in seawater and freshwater. This model translates levels of atmospheric CO<sub>2</sub> into changes in ocean pH. A lower ocean pH indicates higher ocean acidity, while a higher pH indicates lower acidity.<sup>33</sup> The model was developed by Brookhaven National Laboratory and Oak Ridge National Laboratory and is used by both the DOE and EPA. Orr et al. (2015) compared multiple ocean carbon system models and found that the CO2SYS model was more efficient at analyzing observed ocean chemistry data than other models.

This model uses two of four measurable parameters of the CO<sub>2</sub> system (total alkalinity, total inorganic CO<sub>2</sub>, pH, and either fugacity or partial pressure of CO<sub>2</sub>) to calculate the remaining two input parameters. NHTSA used the CO2SYS model to estimate the pH of ocean water in the year 2040, 2060, and 2100 under the relevant No-Action Alternative and each of the action alternatives. For each action alternative, total alkalinity and partial pressure of CO<sub>2</sub> were selected as inputs. The total alkalinity input was held constant at 2,345 micromoles per kilogram of seawater and the projected atmospheric CO<sub>2</sub> concentration (ppm) data was obtained from MAGICC model runs using each action alternative. NHTSA then compared the pH values calculated from each action alternative to the relevant No-Action Alternative to determine the impact of the Proposed Action and alternatives on ocean pH.

### **E.4.3.4 Global Emissions Scenarios**

In 2003, CCSP released the *Strategic Plan for the U.S. Climate Change Science Program* (CCSP 2003), which called for the preparation of 21 synthesis and assessment products addressing a variety of topics on climate change science, GHG mitigation, and adapting to the impacts of climate change. These scenarios used updated economic and technology data along with improved scenario development tools that incorporated knowledge gained over the years since the *IPCC Special Report on Emissions Scenarios* (IPCC 2000) was released. The strategy recognized that it would be important to have a consistent set of emissions scenarios so the whole series of synthesis and assessment products would have the same foundation. Three climate-modeling groups independently produced a unique emissions reference scenario with no implemented climate policies beyond the current set of policies in place and four additional stabilization scenarios with varying long-term radiative impacts for GHGs (CO<sub>2</sub>, N<sub>2</sub>O, CH<sub>4</sub>, hydrofluorocarbons [HFCs], perfluorocarbons, and sulfur hexafluoride). The no climate policy scenario

---

<sup>31</sup> SSP1-1.9, SSP1-2.6, SSP2-4.5, SSP3-7.0, and SSP5-8.5.

<sup>32</sup> The MAGICC model runs simulations from a preindustrial starting point through the year 2100. Results of this analysis are shown for the years 2040, 2060, and 2100.

<sup>33</sup> Preindustrial average ocean pH was 8.2. The average pH of the world's oceans has decreased by 0.1 unit compared to the preindustrial period, bringing ocean pH to 8.1 (IPCC 2021a).

uses a set of assumptions about drivers such as population changes, economic growth, land and labor productivity growth, technological options, and resource endowments. The four additional stabilization scenarios represent various levels of implementation of global GHG emissions reduction policies and have been continuously updated with subsequent IPCC reports.

AR6 uses updated Global Climate Models and GHG concentration scenarios developed for the CMIP6. The newest GHG concentration scenarios are called SSPs and are designed to provide an expanded set of GHG concentrations based on a range of future socioeconomic conditions (Riahi et al. 2017). The SSPs are a series of projections representing a range of future climate change scenarios and development pathways that encompass various trajectories of global GHG emissions. Developed using complex Integrated Assessment Models, these pathways make assumptions about how population, education, energy use, technology, and more, could change over the next century and are coupled with assumptions about the level of ambition for and success with mitigating climate change. These socioeconomic factors and mitigation ambitions are translated into projections of future GHG emissions and resulting changes to climate indicators (Harrison 2021).

NHTSA adjusted the reference datasets to use these SSP scenarios in place of the previous RCP scenarios, which explore the effects of different emissions trajectories, resulting in various radiative forcing values.<sup>34</sup> However, unlike in SSPs, the socioeconomic characteristics that define RCPs are not standardized, making it difficult to map societal changes.

First, SSPs lay out possible socioeconomic conditions, land-use changes, and other human-caused climate drivers that influence GHG emissions, affecting ERF. Second, they describe socioeconomic characteristics that influence GHG emissions in a standardized manner, indicating the societal pathways associated with different levels of warming. Potential mitigation actions, such as limiting global temperature rise to below 2°C above preindustrial levels, can be “applied” within these baseline socioeconomic scenarios to evaluate their effectiveness in achieving various targets. Illustrated in Figure E.4.3-1 are temperature levels relative to preindustrial levels with historical temperatures (front light-yellow band), 2020 temperatures (white block in the middle) and branching of the respective scenarios over the 21st century along the five different SSP scenarios.

---

<sup>34</sup> “Radiative forcing (RF) describes the change in the net downward radiative flux from the top of the atmosphere after allowing for atmospheric temperatures, water vapor and clouds to adjust, but with surface temperature or a portion of surface conditions unchanged. All surface and tropospheric conditions are kept fixed for RF, whereas effective radiative forcing (ERF) allows all physical variables to respond to perturbations, except for those concerning the ocean and sea ice” (IPCC 2021a). The SSP scenarios model ERF, while previous RCP scenarios modeled RF.

Figure E.4.3-1. The SSP Scenarios and Their Five Socioeconomic SSP Families

Source: Meinshausen et al. 2020  
 SSP = Shared Socioeconomic Pathway

A set of SSPs provide continuity with RCPs by modeling similar ERFs through the end of this century (e.g., SSP5-8.5 is a companion to RCP8.5). SSPs also consider a greater range of future aerosol concentrations, which drives a greater range of temperature projections (Riahi et al. 2017). The core set of five SSP scenarios in AR6 (SSP1-1.9, SSP1-2.6, SSP2-4.5, SSP3-7.0, SSP5-8.5) were chosen to ensure overlap with the existing RCP levels of ERF in the year 2100, while simultaneously presenting a broader array of potential mitigation and adaptation possibilities.

CMIP6 model ensembles using SSPs yield greater warming and a larger range of projected temperature and precipitation outcomes than the Coupled Model Intercomparison Project Phase 5 (CMIP5). Specifically, CMIP6 models project greater warming at the upper end of the 5 percent to 95 percent ensemble envelope for the high SSP5-8.5 scenario, and individual global climate models using SSP5-8.5 simulate warming greater than previously predicted (Tebaldi et al. 2021). For instance, the upper end (95th percentile) of warming through the end of the century under SSP5-8.5 is 5.7°C (10.3°F) (IPCC 2021b), while warming under RCP8.5 is 4.8°C (8.6°F) (IPCC 2013b). CMIP6 models also have larger climate sensitivities than CMIP5 (Zelinka et al. 2020; Hermans et al. 2021), meaning that, on average, CMIP6 models simulate larger global temperature change in response to increases in CO<sub>2</sub> concentrations. For example, effective climate sensitivity corresponding to CO<sub>2</sub> quadrupling increased from 3.7 to 8.4°F in CMIP5 to 3.2 to 10.1°F in CMIP6 (Zelinka et al. 2020).

MAGICC uses the SSP long-term emissions scenarios that represent different assumptions about key drivers of GHG emissions. As explained in more detail below, the direct and indirect impacts analysis uses the SSP3-7.0 scenario, and the cumulative impacts analysis uses the SSP2-4.5 scenario to represent

reference case global emissions scenarios. NHTSA chose the SSP3-7.0 scenario as a reference case for the direct and indirect impacts analysis for its incorporation of a comprehensive suite of GHG and pollutant gas emissions, including carbonaceous aerosols and a global context of emissions with a full suite of GHGs and ozone precursors. The SSP3-7.0 scenario yields an ERF of approximately 7.0 W/m<sup>2</sup> in the year 2100 and it is noted in the IPCC WGI AR6 as being a high emissions scenario, “in between RCP6.0 and RCP8.5.” That assumes no successful, comprehensive global actions to mitigate GHG emissions (IPCC 2021a). SSP2-4.5 was chosen as a reference case for the cumulative impacts analysis because the scenario assumes an intermediate level of emissions with significant global cooperation to address climate change. Sections E.4.3.4.1, *Global Emissions Scenario Used for the Direct and Indirect Impacts Analysis*, through E.4.3.4.3, *Other Past, Present, and Reasonably Foreseeable Future Actions*, describe the differences among these scenarios and provide the rationale for use in each analysis.

#### **E.4.3.4.1 Global Emissions Scenario Used for the Direct and Indirect Impacts Analysis**

The results of the direct and indirect impacts analysis rely on the SSP3-7.0 scenario to represent a high reference case emissions scenario resulting from limited global cooperation on emissions mitigation efforts under the SSP3 socioeconomic development narrative. This scenario replaces the GCAMReference scenario used in the previous analysis. This scenario assumes there are no successful, comprehensive global actions to mitigate GHG emissions and yields atmospheric CO<sub>2</sub> levels of 800 ppm and an ERF of 7.0 W/m<sup>2</sup> in 2100. SSP3-7.0 has particularly high non-CO<sub>2</sub> emissions, including high aerosols emissions, which continue to increase over the 21st century. The IPCC refers to SSP3-7.0 as a high emissions scenario, where CO<sub>2</sub> emissions roughly double current levels by 2100, but increase less rapidly than the very high SSP5-8.5 scenario.

SSP3, the regional rivalry scenario, centers around high challenges to mitigation and adaptation. Policies are focused on security with significant barriers to international trade, high inequality, slow economic growth, low population growth in rich countries, and high population growth in the developing world. The pathway represents concerns about competitiveness and security, and policies become increasingly oriented toward national and regional security issues with countries focusing on energy and food security within their own regions, at the expense of broader development. Educational and technological investments decline, and economic development is slow. Consumption is material-intensive and there is a low international priority for addressing environmental concerns, leading to inequalities and strong environmental degradation in some regions (Riahi et al. 2017). SSP3 has higher climate mitigation costs and shows high challenges to adaptation in terms of income and trade features. Unlike SSP5, which faces high challenges to mitigation and low challenges to adaptation, fossil fuel use does not intensify in SSP3 and therefore there is less intense warming. Furthermore, SSP3 does not see inequality deepen as much as the SSP4 pathway, which faces low challenges to mitigation and high challenges to adaptation. SSP4 and SSP5 include distinctly bleaker views of a world with limited technology improvements and continued business-as-usual emissions projections (Fujimori et al. 2017).

The impact of each action alternative was simulated by calculating the difference between annual GHG emissions under the relevant No-Action Alternative and emissions under the action alternative and subtracting this change from the selected scenarios to generate modified global-scale emissions scenarios, which show the effects of the various regulatory alternatives on the global emissions path. The same methodology was used to analyze the impact of action alternatives under the CAFE standards, the HDPUV FE standards, and the combined set of alternatives.

For example, CO<sub>2</sub> emissions from passenger cars and LD trucks in the United States in 2040 under the No-Action Alternative are estimated to be 900 million metric tons carbon dioxide (MMTCO<sub>2</sub>); the

emissions in 2040 under Alternative PC2LT4 (Preferred Alternative for CAFE standards) (Chapter 2, Section 2.2, *Proposed Action and Alternatives*) are estimated to be 883 MMTCO<sub>2</sub>. For HDPUVs in the United States, CO<sub>2</sub> emissions in 2040 are estimated to be 145 MMTCO<sub>2</sub> under the No-Action Alternative and 142 MMTCO<sub>2</sub> under Alternative HDPUV10 (Preferred Alternative for HDPUV FE standards). Combining all vehicle classes, CO<sub>2</sub> emissions are estimated to be 1,045 MMTCO<sub>2</sub> in 2040 under the No-Action Alternative and 1,025 MMTCO<sub>2</sub> under the Preferred CAFE and Preferred HDPUV FE Alternatives. Therefore, projected emissions are expected to be 17 MMTCO<sub>2</sub> lower for passenger cars and LD trucks, 3 MMTCO<sub>2</sub> lower for HDPUVs, and 20 MMTCO<sub>2</sub> lower for both combined as a result of adopting the Preferred Alternative.

Global emissions in 2040 are estimated to be 58,498 MMTCO<sub>2</sub> under the SSP3-7.0 scenario. These global emissions are assumed to incorporate emissions from passenger cars, LD trucks, and HDPUVs in the United States under the No-Action Alternatives for the CAFE standards and HDPUV FE standards. Therefore, global emissions under the Preferred Alternative for all vehicle classes are estimated to be 20 MMTCO<sub>2</sub> less than the reference levels, or approximately 58,478 MMTCO<sub>2</sub> for SSP3-7.0 in 2040.

There are some inconsistencies between the overall assumptions used to develop SSP3-7.0 used by AR6 and the assumptions used in the CAFE Model in terms of economic growth, energy prices, energy supply, and energy demand. However, these inconsistencies affect the characterization of each action alternative in equal proportion, so the relative estimates provide a reasonable approximation of the differences in environmental impacts among the action alternatives.

#### ***E.4.3.4.2 Global Emissions Scenario Used for the Cumulative Impacts Analysis***

The cumulative impacts analysis relies primarily on the SSP2-4.5 scenario to represent a reference case global emissions scenario that assumes a moderate level of global actions to address climate change and predicts CO<sub>2</sub> emissions would remain around current levels before starting to fall mid-century. The IPCC refers to SSP2-4.5 as an intermediate emissions scenario. NHTSA chose this scenario as a plausible global emissions baseline for the cumulative analysis because of the potential impacts of these reasonably foreseeable actions, yielding a moderate level of global GHG reductions from the SSP3-7.0 baseline scenario used in the direct and indirect analysis. The SSP2-4.5 scenario serves as a reference scenario against which the climate impacts of the Proposed Action and alternatives can be measured. This scenario yields atmospheric CO<sub>2</sub> levels of 568 ppm and an ERF of approximately 4.5 W/m<sup>2</sup> in the year 2100.

The timeframe for this analysis extends from 2040 through 2100 and the geographic area of interest is domestic and global because cumulative impacts of changes in GHG emissions occur on a domestic and global scale. This temporal and geographic focus is consistent with the analysis of direct and indirect GHG and climate change impacts as discussed in Chapter 5, *Greenhouse Gas Emissions and Climate Change*. Specific actions that support the use of the scenarios used in this analysis were included as examples in Section E.4.3.4.3, *Other Past, Present, and Reasonably Foreseeable Future Actions*. The methods NHTSA used to characterize the impacts of the Proposed Action and alternatives on climate are described above. The methods and assumptions for the cumulative analysis are largely the same as those used in the direct and indirect impacts analysis, except (1) the global emissions scenario used for the main cumulative analysis is SSP2-4.5, and (2) multiple global emissions scenarios are modeled in the sensitivity analysis.

SSP2, the middle of the road scenario, considers medium challenges to mitigation and adaptation that continue with current development patterns (Fricko et al. 2017). The pathway represents a world in

which social, economic, and technological trends do not shift markedly from historical patterns. Development and income growth proceed unevenly; institutions make slow progress in achieving sustainable development goals; environmental systems experience degradation, although there are some improvements; and overall, resource and energy use declines. Global population growth levels off in the second half of the century and income inequality persists or slowly improves, with challenges to reducing vulnerability to societal and environmental changes remaining (Riahi et al. 2017). Thus, NHTSA believes that SSP2-4.5 represents reasonable proxies for the past, present, and reasonably foreseeable GHG emissions through 2100, and is used for that purpose in this cumulative impact analysis on GHG emissions and climate change.

For the cumulative impact analysis, NHTSA calculated the difference in annual GHG emissions under the Proposed Action and alternatives compared to the relevant No-Action Alternative. NHTSA applied this change to the SSP2-4.5 scenario to generate modified global-scale emissions scenarios, which show the impact of the Proposed Action and alternatives on the global emissions paths.

For example, CO<sub>2</sub> emissions from passenger cars and LD trucks in the United States in 2040 under the No-Action Alternative are estimated to be 900 MMTCO<sub>2</sub>; the emissions in 2040 under Alternative PC2LT4 (Preferred Alternative for CAFE standards) (Chapter 2, Section 2.2, *Proposed Action and Alternatives*) are estimated to be 883 MMTCO<sub>2</sub>. For HDPUVs in the United States, CO<sub>2</sub> emissions in 2040 are estimated to be 145 MMTCO<sub>2</sub> under the No-Action Alternative and 142 MMTCO<sub>2</sub> under Alternative HDPUV10 (Preferred Alternative for HDPUV FE standards). Combining all vehicle classes, CO<sub>2</sub> emissions are estimated to be 1,045 MMTCO<sub>2</sub> in 2040 under the No-Action Alternative and 1,025 MMTCO<sub>2</sub> under the Preferred CAFE and Preferred HDPUV FE Alternatives. Therefore, projected emissions are expected to be 17 MMTCO<sub>2</sub> lower for passenger cars and LD trucks, 3 MMTCO<sub>2</sub> lower for HDPUVs, and 20 MMTCO<sub>2</sub> lower for both combined as a result of adopting the Preferred Alternative.

Global emissions in 2040 are estimated to be 44,253 MMTCO<sub>2</sub> under the SSP2-4.5 scenario. These global emissions are assumed to incorporate emissions from passenger cars, LD trucks, and HDPUVs in the United States under the No-Action Alternatives for the CAFE standards and HDPUV FE standards. Therefore, global emissions under the Preferred Alternative for all vehicle classes are estimated to be 20 MMTCO<sub>2</sub> less than the reference levels, or approximately 44,233 MMTCO<sub>2</sub> for SSP2-4.5 in 2040.

To evaluate the sensitivity of the results to a reasonable range of alternative emissions scenarios, NHTSA also used the SSP1-2.6 and SSP3-7.0 scenarios. The SSP1-2.6 scenario is considered a more aggressive stabilization scenario that illustrates a “green growth strategy” that stabilizes the anthropogenic components of ERF at 2.6 W/m<sup>2</sup> and has atmospheric CO<sub>2</sub> levels at 437.66 ppm in 2100. In this scenario, there are low challenges to adaptation and mitigation. The scenario is used in place of the optimistic RCP2.6 scenario and was designed with the aim of simulating a development that is compatible with a 2°C target.

SSP1, the sustainability scenario, is based on minimal challenges to mitigation and adaptation, policy focused on sustainable development, effective international cooperation, reduced inequality, low consumption, and low population growth. The pathway represents a world that shifts gradually toward a more sustainable path, emphasizing development that respects environmental boundaries. Resource management slowly improves, investments in education and health accelerate the demographic transition, and the emphasis on economic growth shifts toward human well-being. Driven by an increasing commitment to achieving development goals, inequality is reduced both across and within countries, and consumption is oriented toward lower material growth and resource and energy intensity (Riahi et al. 2017).

This green growth paradigm shows how GHG and air pollutant emissions and global land use could develop in very different directions based on societal trends in the energy and agriculture sectors. SSP1 shows how a combination of resource efficiency, preferences for sustainable production methods, and investment in human development could lead to lower anthropogenic GHG emissions and land use in 2100 than in 2010. This scenario could be a basis for further discussion on how climate policy can be combined with achieving other societal goals (van Vuuren et al. 2017).

#### ***E.4.3.4.3 Other Past, Present, and Reasonably Foreseeable Future Actions***

NHTSA chose the SSP2-4.5 scenario as the primary global emissions scenarios for evaluating climate impacts for the cumulative impacts analysis because regional, national, and international initiatives and programs now in the planning stages or already underway indicate that a moderate reduction in the growth rate of global GHG emissions is reasonably foreseeable in the future.

The following initiatives and programs are evidence of the past, present, or reasonably foreseeable future actions that would affect GHG emissions. Global and domestic actions to reduce GHG emissions indicate that a moderate reduction in the growth rate of global GHG emissions is reasonably foreseeable in the future. NHTSA used these scenarios to assess the impacts of the Proposed Action and alternatives when reasonably foreseeable increases in global GHG emissions are taken into account. Although it is not possible to quantify the precise GHG effects associated with these actions, policies, or programs when taken together (and NHTSA does not attempt to do so), collectively they illustrate an existing and continuing trend of U.S. and global awareness, emphasis, and efforts toward substantial GHG reductions. Therefore, a scenario that accounts for an intermediate emissions pathway with moderate reductions in the rate of global GHG emissions, such as the SSP2-4.5 scenario, can be considered reasonable under NEPA.

#### **United States: Regional and State Actions**

The following actions in the United States are already underway or reasonably foreseeable.

- **Regional Greenhouse Gas Initiative (RGGI).** Launched on January 1, 2009, RGGI was the first mandatory, market-based effort in the United States to reduce GHG emissions (RGGI 2009). The initiative now includes the following 12 Northeast and Mid-Atlantic states: Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont, and Virginia.<sup>35</sup> Initially, RGGI states agreed to cap annual emissions from power plants in the region at 188 MMTCO<sub>2</sub> for 2009 through 2011, and 165 MMTCO<sub>2</sub> for 2012 through 2013 (RGGI 2014; Block 2014). In 2013, RGGI states lowered the regional emissions cap to 91 MMTCO<sub>2</sub> for 2014. The RGGI CO<sub>2</sub> cap then declined 2.5 percent per year from 2015 through 2020 (RGGI 2021). RGGI states plan to reduce the overall cap by 30 percent between 2020 and 2030 (RGGI 2021). The proposed changes include an 11-state cap of 119.8 MMTCO<sub>2</sub> in 2021, which will decline to 86.9 MMTCO<sub>2</sub> in 2030 (RGGI 2021). Including Pennsylvania, the 2022 cap was 156.8

---

<sup>35</sup> New Jersey was a part of RGGI at its founding but dropped out of the program in May 2011. On January 29, 2018, New Jersey Governor Phil Murphy signed an executive order directing the state to rejoin RGGI, and the state officially rejoined in 2019. Virginia joined RGGI in July 2020. On October 3, 2019, Pennsylvania Governor Tom Wolf issued an executive order instructing the state's Department of Environmental Protection to join RGGI. In April 2022 the state officially joined; however, as of July 2022, the Commonwealth Court of Pennsylvania reinstated an injunction on implementation and enforcement of RGGI regulation (PA DEP 2022).

MMTCO<sub>2</sub>; however, due to a Pennsylvania court injunction, Pennsylvania is not releasing any allowances during 2022. Therefore, the 11-state cap was 116.1 MMTCO<sub>2</sub> in 2022 (RGGI 2022).

- **California 2016 Greenhouse Gas Reduction Legislation (Senate Bill 32).** In 2016, California passed Senate Bill 32, which codifies into law a GHG emissions reduction target of 40 percent below 1990 levels by 2030, equivalent to an absolute level of 260 MMTCO<sub>2</sub>e (California Air Resources Board [CARB] 2017). Initiatives to support this goal seek to reduce GHGs from cars, trucks, electricity production, fuels, and other sources. GHG-reduction measures under CARB's 2017 proposed scoping plan update include a continuation of the state's cap-and-trade program, a renewables portfolio standard, reduction of electric sector GHG emissions through the integrated resources plan process, low carbon fuel standards, zero-emission and plug-in hybrid LD electric vehicle (EV) deployment, medium- and heavy-duty vehicle GHG regulations, VMT reduction programs, the Short-Lived Climate Plan to reduce non-CO<sub>2</sub> GHGs, and refinery sector GHG regulations (CARB 2017).<sup>36</sup> CARB released a proposed scoping plan update in 2022 that supported a goal of 100 percent zero-emission sales of LD vehicles by 2030 and medium- and heavy-duty vehicles by 2040, a 20 percent zero-emission target for the aviation transportation sector, and reduced per capita VMT by 25 percent of 2019 levels by 2030 (CARB 2022a). Each of these measures is either a known commitment, already underway, or required. The cap-and-trade program took effect in 2013 for electric generation units and large industrial facilities and expanded in 2015 to include ground transportation and heating fuels (C2ES 2014). The known commitments are projected to reduce GHG emissions by 48 percent of 1990 levels by 2030 (CARB 2022b).
- **U.S. Climate Alliance.** Twenty-four U.S. governors have committed to reduce GHG emissions in their respective jurisdictions consistent with the goals of the Paris Agreement. Alliance members have committed to implement policies that will reduce emissions at least 50 to 52 percent below 2005 levels by 2030 and achieve overall net-zero emissions as soon as practicable and before 2050 (U.S. Climate Alliance 2021). In 2005, emissions from Alliance members totaled approximately 2.8 gigatons (Gt) of CO<sub>2</sub> (U.S. Energy Information Administration 2018a, 2018b). From 2005 to 2020, Alliance members reduced emissions by 24 percent (U.S. Climate Alliance 2022). Based on policies in place in 2022, Alliance members are projected to achieve the reduction target of 26 to 28 percent below 2005 levels by 2025 (U.S. Climate Alliance 2022).
- **Zero-Emission Vehicle (ZEV) Mandates.** In March 2012, California Governor Jerry Brown issued an Executive Order (E.O.) establishing several milestones on a path toward 1.5 million ZEVs in California by the year 2025 (California Office of the Governor 2013). Since 2013, California has created three ZEV action plans for obtaining this goal and introducing new goals; most recently with the goal of 5 million ZEVs by 2030 (California Governor's Office of Business and Economic Development 2021). In addition to these goals, California has issued several mandates with more details on California's ZEV plans of action. In 2015, the state updated the California Code of Regulations (CCR) at 13 CCR § 1962.2, which regulated the minimum ZEV credit percentage requirements for passenger cars, LD trucks, and medium-duty vehicles for MY 2018 and later. In 2018, this ZEV minimum percentage requirement was 4.5 percent, increasing to 22.5 percent for MY 2025 and beyond. In September 2020, California Governor Gavin Newsom established through E.O. N-79-20 new targets for ZEVs including 100 percent of in-state sales of new passenger vehicles and drayage trucks to be zero-

---

<sup>36</sup> In September 2019, NHTSA issued a final rule that established regulatory text explicitly preempting state and local laws relating to fuel economy standards established under the Energy Policy and Conservation Act. As part of that action, EPA also withdrew the waiver it had previously provided to California for that State's GHG and ZEV programs under Section 209 of the Clean Air Act. The Safer Affordable Fuel-Efficient (SAFE) Vehicles Rule Part One: One National Program; Final Rule, 84 FR 51310 (Sept. 27, 2019).

emission by 2035, with medium- and heavy-duty vehicles to follow in 2045 (California Governor’s Office of Business and Economic Development 2021). As of 2022, 14 states (the “Section 177” states<sup>37</sup>), making up more than one-third of total new car sales in the United States, have adopted either ZEV mandates identical to California’s or ones with variations (C2ES 2022).

- **California Actions on Emissions.** In August 2020, California formalized bilateral agreements with six automakers to continue its emissions reduction framework developed in 2019 (CARB 2019). These six automakers are BMW (of America), Ford, Honda, Volkswagen (of America), Audi, and Volvo. The framework agreement continues annual reductions of LD vehicle GHG emissions through MY 2026 under approximately the same rates as the standards set by EPA in 2012 (CARB 2020). The states that have previously adopted these California standards (the same 13 that adopted the ZEV mandates) have also supported California’s GHG vehicle framework agreements. In March 2022, EPA confirmed the Clean Air Act (CAA) waiver of preemption for California’s ZEV sales mandate and GHG emissions standards.<sup>38</sup>

### United States: Federal Actions

The following Federal actions are already underway or reasonably foreseeable.

- **NHTSA Fuel Economy Standards for MYs 2024–2026.** On March 31, 2022, NHTSA issued this final rule to establish standards that would require an industry-wide fleet average of approximately 49 mpg for passenger cars and light trucks in MY 2026, by increasing fuel efficiency by 8 percent annually for MYs 2024 and 2025, and 10 percent annually for MY 2026. The agency projects the final standards will avoid consumption of about 234 billion gallons of gas between MYs 2030 and 2050, and will reduce CO<sub>2</sub> emissions by 2.5 billion metric tons. EPA issued a separate final rule setting GHG standards for passenger cars and light trucks for MYs 2023 through 2026.<sup>39</sup>
- **NHTSA Fuel Efficiency (FE) and GHG Standards for Medium- and Heavy-Duty Engines and Vehicles and the EPA Clean Trucks Plan.** NHTSA, in coordination with EPA and in response to the requirements in the Energy Independence and Security Act (EISA) of 2007, intends to propose new FE standards for MYs 2030 and beyond for medium- and heavy-duty vehicles by July 2024.<sup>40</sup> Through this, NHTSA will propose the next phase (Phase 3) of the Medium and Heavy Vehicle Fuel Efficiency Standards program. In Phase 2, NHTSA tailored the standards to different regulatory categories of HD vehicles based on fuel type, duty cycle, vehicle application, etc., and is currently seeking comments on how to tailor Phase 3 FE standards to these regulatory categories. In August 2021, EPA also announced the Clean Trucks Plan, which aims to reduce GHG emissions and other air pollutants from HD trucks through a series of rulemakings over 3 years. The regulatory actions include setting stronger NO<sub>x</sub> standards for HD trucks and tightening “Phase 2” GHG emissions beginning in MY 2027, setting stronger emissions standards for medium-duty commercial vehicles beginning in MY 2027, and setting “Phase 3” GHG standards for HD vehicles beginning in MY 2030

---

<sup>37</sup> *Section 177 states* refers to the U.S. states that have adopted California’s criteria pollutant and GHG emissions regulations under Section 177 of the Clean Air Act (42 U.S.C. 7507).

<sup>38</sup> *California State Motor Vehicle Pollution Control Standards; Advanced Clean Car Program; Reconsideration of a Previous Withdrawal of a Waiver of Preemption; Notice of Decision*, 87 FR 14332 (Mar. 14, 2022).

<sup>39</sup> *Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards; Final Rule*, 86 FR 74434 (Dec. 30, 2021).

<sup>40</sup> NHTSA Fuel Efficiency and Greenhouse Gas Standards for Medium and Heavy-Duty Engines and Vehicles <https://www.regulations.gov/document/NHTSA-2022-0076-0001>.

that are significantly stronger than the MY 2027 GHG standards (EPA 2021g). In December 2022, EPA finalized the strongest-ever national clean air standards to cut smog- and soot-forming emissions from HD trucks beginning with MY 2027, as part of this plan (EPA 2022n).

- **NHTSA and EPA Joint Rule on Fuel Economy and GHG Emissions Standards for LD Vehicles.** In August 2012, NHTSA and EPA issued joint final rules to further improve the fuel economy of and reduce CO<sub>2</sub> emissions for passenger cars and light trucks, as described in Chapter 1, *Purpose and Need for the Action*. The standards were projected to reduce average CO<sub>2</sub> emissions from new U.S. LD vehicles by 3.5 percent per year for MYs 2017–2021 (NHTSA and EPA 2011). Since the implementation of this joint rule, 10 of the 14 largest vehicle manufacturers selling cars in the U.S. market have made improvements to both fuel economy and CO<sub>2</sub> emissions. Between 2012 and 2019, the industry decreased CO<sub>2</sub> emissions by 21 gallons per mile and increased fuel economy by 1.3 mpg (EPA 2020l).
- **NHTSA and EPA Joint Phase 1 Rule on GHG Emissions and FE Standards for Medium- and Heavy-Duty Vehicles, MYs 2014–2018.** On September 15, 2011, NHTSA and EPA published the Phase 1 joint final rules to establish FE and CO<sub>2</sub> standards for commercial medium- and heavy-duty on-highway vehicles and work trucks. The agencies' standards apply to highway vehicles and engines that are not regulated by the LD vehicle CAFE and CO<sub>2</sub> standards. NHTSA's Phase 1 mandatory standards for HD vehicles and engines began for MY 2016 vehicles, with voluntary standards for MYs 2014–2015. EPA's mandatory standards for HD vehicles began for MY 2014 vehicles. The combined standards were projected to reduce CO<sub>2</sub> emissions by approximately 270 MMTCO<sub>2</sub>e over the lifetime of vehicles built during MYs 2014–2018 (NHTSA 2011).
- **NHTSA and EPA Joint Phase 2 Rule on GHG Emissions and FE Standards for Medium- and Heavy-Duty Vehicles, MYs 2018–2027.** In August 2016, NHTSA and EPA published the Phase 2 joint final rule to reduce fuel consumption and GHG emissions from HD vehicles. As with the Phase 1 standards, the Phase 2 fuel consumption and CO<sub>2</sub> standards apply to highway vehicles and engines that are not regulated by the LD vehicle CAFE and CO<sub>2</sub> standards. NHTSA and EPA Phase 2 standards apply to MYs 2021–2027 for HD vehicle engines, Classes 7 and 8 tractors (combination heavy-haul tractors), Classes 2 through 8 vocational vehicles (buses and work trucks), and Classes 2b and 3 HDPUVs (large pickup trucks and vans). The combined standards were projected to reduce GHG emissions by approximately 1,100 MMTCO<sub>2</sub>e over the lifetime of vehicles sold during MYs 2018–2027 (NHTSA 2016b).
- **E.O. 14037, Strengthening American Leadership in Clean Cars and Trucks.** In E.O. 14037,<sup>41</sup> President Biden directed NHTSA and EPA to consider multiple actions to regulate the fuel efficiency of and CO<sub>2</sub> emissions from post-MY 2026 light-, medium-, and heavy-duty vehicles.
- **Renewable Fuel Standard 2 (RFS2).** Section 211(o) of the CAA requires that a renewable fuel standard be determined annually that is applicable to refiners, importers, and certain blenders of gasoline and diesel fuel. Based on this standard, each obligated party determines the volume of renewable fuel that it must ensure is consumed as motor vehicle fuel. RFS2, which went into effect July 1, 2010, increases the volume of renewable fuel required to be consumed in the transportation sector from the baseline of 9 billion gallons in 2008 to 36 billion gallons by 2022, as written in 2010. Since 2014, the volumetric requirements have been modified to account for lower-than-expected growth in advanced and cellulosic biofuels (EPA 2015c).<sup>42</sup> The increased use of renewable fuels over

<sup>41</sup> E.O. 14037, Strengthening American Leadership in Clean Cars and Trucks, 86 FR 43583 (Aug. 10, 2021).

<sup>42</sup> <https://www.epa.gov/renewable-fuel-standard-program/final-renewable-fuel-standards-2014-2015-and-2016-and-biomass-based>.

30 years, given a zero percent discount rate, is projected to reduce GHG emissions by 4,500 MMTCO<sub>2</sub>e.

- **U.S. Appliance and Equipment Standards Program.** The National Appliance Energy Conservation Act of 1987 established minimum efficiency standards for many household appliances and has been authorized by Congress through several statutes. Since its inception, the program has implemented additional standards for more than 60 products, which represent about 90 percent of home energy use, 60 percent of commercial building use, and 30 percent of industrial energy use (DOE 2017). The program has avoided more than 3,000 MMTCO<sub>2</sub> and is expected to reduce GHG emissions by 7,900 MMTCO<sub>2</sub>e annually by 2030 (DOE 2016).
- **Final Rule to Redefine Terms under DOE Lighting Efficiency Standards.** In 2007, EISA directed DOE to conduct a rulemaking on efficiency standards for general service lamps (GSLs) and other incandescent lamps. In January 2017, DOE issued a final rule that revised and expanded the definition for GSL to include a broader range of incandescent lightbulbs, including those used for decorative and less-common purposes than general lighting (EPA 2017b). In February 2019, DOE issued a notice of proposed rulemaking to rescind the 2017 amendments, arguing that the definition revisions were not lawful according to the 2007 rulemaking directive (EPA 2019c). The rule to rescind the amendments was finalized in September 2019. The energy savings potential of the 2017 standards was estimated to be 27 quadrillion BTUs for lamps shipped between 2020 and 2049 (Kantner et al. 2017). The proposal had the potential to reduce GHG emissions by 540 MMTCO<sub>2</sub>e by 2030 (Kantner et al. 2017). In May 2021, DOE announced that it is re-evaluating its determination from 2019—that the Secretary of Energy was not required to implement the statutory backstop requirement for GSLs—possibly reinstating the 2017 revision (DOE 2021b). On May 9, 2022, the proposed rulemaking was finalized by DOE to reinstate the 2017 revision for GSLs and other supplemental definitions. This final rule entered effect in July 2022 (DOE 2022j).
- **Revisions to the Methane New Source Performance Standards (NSPS) Rule.** In 2016, the NSPS rule that targets controlling CH<sub>4</sub> and VOC leaks from oil and gas operations was finalized. In 2020, EPA issued two final rules that amended the 2016 NSPS. The first, published on September 14, 2020, finalized changes to the prior standards that remove oil and gas transmission and storage operations and associated CH<sub>4</sub> emissions limits (policy amendments final rule).<sup>43</sup> The second, published on September 15, 2020, finalized technical changes to the prior standards that lowered leak mitigation requirements for compressor stations in the oil and gas industry and eliminated leak mitigation requirements for the industry’s low-production wells, among other changes (technical amendments final rule).<sup>44</sup> In June 2021, President Biden signed a Congressional Review Act resolution to disapprove (repeal) the policy amendments final rule.<sup>45</sup> EPA has announced its intention to reconsider the technical amendments final rule.<sup>46</sup> If the technical amendments final rule remains in place, CH<sub>4</sub> emissions can be expected to increase by 10 MMTCO<sub>2</sub>e by 2030.<sup>47</sup> In November 2021, EPA proposed a new rule that would significantly reduce emissions from the crude oil and natural

<sup>45</sup> Pub. L. No. 117-23, S.J.Res.14 (June 30, 2021).

<sup>46</sup> Spring 2021 Unified Agenda of Regulatory and Deregulatory Actions, RIN 2060-AV16. Available at: <https://www.reginfo.gov/public/do/eAgendaMain> (last accessed June 22, 2021).

<sup>47</sup> *Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Source Reconsideration; Final Rule*, 85 FR 57398, 57434 (Sept. 15, 2020).

gas industries.<sup>48</sup> The rule would revise NSPS for new sources and propose guidelines under the CAA for states to follow in developing new performance standards for existing sources. In total, this action could reduce CH<sub>4</sub> emissions by 41 million tons through 2035 (EPA 2021h). On December 6, 2022, EPA issued a supplement to this proposed rulemaking to expand the rule to additional sources, strengthen the standards, make amendments in response to public comments, and propose a timeline and other implementation requirements for states (EPA 2022o).

- **Infrastructure Investment and Jobs Act.**<sup>49</sup> On November 15, 2021, the Infrastructure Investment and Jobs Act was signed into law. This bipartisan infrastructure bill authorizes funds for Federal-aid highways, highway safety programs, and public transit programs. Among other provisions, this legislation will invest \$7.5 billion to build a network of EV chargers in the United States and \$39 billion to improve public transit infrastructure in addition to the reauthorization of existing transit programs. This investment will include replacing existing public vehicles with ZEVs, as well as expanding and improving public transit options across the country, including the largest investment in passenger rail since Amtrak was authorized in 1970. The transportation sector is the largest single source of GHG emissions in the United States. Improving access to and quality of public transit systems will reduce GHG emissions via reduced dependency on single-occupancy vehicles. The bill also aims to build more climate-resilient transmission lines to facilitate the expansion of renewables at lower costs. Combined with the Inflation Reduction Act (IRA), actions from these two pieces of legislation are estimated to reduce emissions by 1,150 MMTCO<sub>2e</sub> in 2030 (DOE 2022k).
- **E.O. 14008, Tackling the Climate Crisis at Home and Abroad.** President Biden signed E.O. 14008 on January 27, 2021, to prioritize tackling climate change in both domestic and international policy.<sup>50</sup> The E.O. takes a whole-of-government approach to addressing climate change, establishing the White House Office of Domestic Climate Policy, the National Climate Task Force, and other interagency working groups to facilitate a cohesive government-wide approach to climate change that prioritizes job creation, economic opportunity, and environmental justice.
- **Inflation Reduction Act.** In August 2022, the IRA was signed into law, representing the most significant action Congress has yet to take on clean energy and climate change. The IRA is a 10-year plan that includes \$369 billion in clean energy programs and incentives (e.g., tax credits) across the U.S. economy, including in the power, industry, buildings, transportation, and agriculture and forestry sectors. The IRA provides clean vehicle credits for new and used EVs; removes the cap for the DOE program that provides loans to facilities manufacturing advanced vehicles that emit a low amount of GHGs or no GHGs; provides incentives to replace eligible medium-duty and HD vehicles with ZEVs; increases funding for the EPA program that gives grants, rebates, and loans under the Energy Policy Act of 2005 to identify and reduce diesel emissions resulting from goods movement facilities and vehicles servicing those facilities in low-income and disadvantaged communities; and provides funding to the U.S. Postal Service for purchasing zero-emission delivery vehicles and installing related infrastructure.<sup>51</sup> Additionally, it builds on the Infrastructure Investment and Jobs Act and advances the Justice 40 Initiative, which commits to delivering 40 percent of the overall benefits of climate, clean energy, and related Federal investments to communities that are

<sup>50</sup> E.O. 14008, *Tackling the Climate Crisis at Home and Abroad*, 86 FR 7619 (January 27, 2021).

<sup>51</sup> *H.R.5376 - inflation reduction act of 2022 - congress*. (n.d.). Retrieved January 20, 2023, from <https://www.congress.gov/bill/117th-congress/house-bill/5376>.

marginalized, overburdened by pollution, and underserved by infrastructure and other basic services (U.S. White House 2023b). Combined with the Infrastructure Investment and Jobs Act, actions from these two pieces of legislation are estimated to reduce emissions by 1,150 MMTCO<sub>2</sub>e in 2030 (DOE 2022k).

- **Regulations on HFCs.** On December 27, 2020, the American Innovation and Manufacturing (AIM) Act was enacted by Congress. The AIM Act directs EPA to address the environmental impact of HFCs by phasing down production and consumption, maximizing reclamation and minimizing releases from equipment, and facilitating the transition to next-generation technologies through sector-based restrictions. Specifically, the AIM Act directs EPA to phase down production and consumption of HFCs to 15 percent of their baseline levels in a stepwise manner by 2036 through an allowance allocation and trading program. On October 11, 2022, EPA published its list of annual HFC allowances for the production and consumption of HFCs in 2023. This action is expected to reduce GHG emissions by 4,700 MMTCO<sub>2</sub> from 2022 to 2050 (EPA 2021i). On October 14, 2021, EPA issued a decision to grant or partially grant petitions requesting EPA restrict the use of HFCs in the refrigeration and air conditioning, aerosols, and foams sectors. EPA will complete a rulemaking within 2 years of the date the petitions were granted. EPA continues to receive, evaluate, and grant or deny petitions within 180 days of receipt.
- **United States and the Paris Agreement.** On April 22, 2021, President Biden submitted a Nationally Determined Contribution to the United Nations Framework Convention on Climate Change (UNFCCC) secretariat, with a target for the United States to achieve a 50 to 52 percent reduction in economy-wide net GHG pollution from 2005 levels by 2030. This target was submitted under the Paris Agreement, which entered into force on November 4, 2016. The United States formally withdrew from the Paris Agreement in November 2020, but then officially rejoined in February 2021. The Paris Agreement's goal is to limit global average temperature increase to well below 2°C (3.6°F) above preindustrial levels and pursue efforts to limit the increase to 1.5°C (2.7°F).
- **The Long-Term Strategy of the United States: Pathways to Net-Zero GHG Emissions by 2050.** In November 2021, the United States submitted its long-term strategy to the UNFCCC, communicating a goal of net-zero emissions by 2050. This document lays out how the United States plans to achieve both the near-term 2030 GHG target and the longer-term 2050 target. To achieve these goals, the long-term strategy lays out multiple pathways the United States could take, all of which include "five key transformations" including decarbonizing electricity, electrifying end uses and switching to clean fuels, cutting energy waste, reducing non-CO<sub>2</sub> emissions, and scaling up CO<sub>2</sub> removal (U.S. State Department and U.S. Executive Office of the President 2021).

### International Actions

The following international actions are already underway or reasonably foreseeable:

- **UNFCCC and the Annual Conference of the Parties.** This international treaty was signed by many countries around the world (including the United States). It entered into force on March 21, 1994, and sets an overall framework for intergovernmental efforts to tackle the challenge posed by climate change (UNFCCC 2002).
- **Kyoto Protocol.** The Kyoto Protocol is an international agreement linked to the UNFCCC. The major feature of the Kyoto Protocol is its binding targets for 37 industrialized countries and the European Community for reducing GHG emissions, which covers more than half of the world's GHG emissions. These reductions amount to approximately 5 percent of 1990 emissions over the 5-year period 2008 through 2012 (UNFCCC 2014). The December 2011 COP-17 held in Durban, South Africa, resulted in

an agreement to extend the imminently expiring Kyoto Protocol. The Doha Amendment, adopted at COP-18 in Doha, Qatar, included new commitments and revised gases for tracking in the Second Commitment Period, whose parties differed from the first (UNFCCC 2014). The Second Commitment Period took effect on January 1, 2013, ran through December 2020, and required parties to reduce emissions by at least 18 percent below 1990 levels by 2020, a metric that was on pace to be exceeded (UNFCCC 2020). The Paris Agreement, ratified in 2015, supersedes the Kyoto Protocol (UN 2022).

- **Paris Agreement.** At COP-21, the Paris Agreement was adopted, which emphasizes the need to limit global average temperature increase to well below 2°C (3.6°F) above preindustrial levels and pursue efforts to limit the increase to 1.5°C (2.7°F). The agreement urged countries to commit to a GHG reduction target by 2020 and to submit a new reduction target that demonstrates progress every 5 years thereafter. The UN will analyze progress on global commitments in 2023 and every 5 years thereafter. As of January 2023, 194 parties (193 countries plus the European Union [EU]), including the United States, comprising over 97 percent of global GHG emissions had ratified, accepted, or approved the Paris Agreement (WRI 2023; UN 2023a). Initial GHG emissions reduction targets announced by country signatories to the Paris Agreement are expected to result in global emissions that are 3.6 Gt lower in 2030 than projected from pre-Paris national pledges (UNFCCC 2015). Based on country pledges from the Paris Agreement, global GHG emissions in 2030 are expected to be lower than those under the highest emissions scenario (RCP8.5) but higher than those under RCP4.5 and RCP6.0 (UNFCCC 2015). While the commitments to reduce GHG emissions cannot be extrapolated into a trend (i.e., there is significant uncertainty surrounding emissions before and after 2030), they demonstrate global action to reduce the historical rate of GHG emissions growth. A recent report by the UN finds that current commitments by the parties, if attained, will limit projected warming to about 2.5°C by 2100, but indicates an urgent need for more ambitious Nationally Determined Contributions (NDCs), or significant overachievement of the most recent NDCs to limit warming to below 2°C (UNFCCC 2022a).
- **Additional UNFCCC and COP Decisions and Actions.** COP-26 emphasized the need to attain net-zero emissions by 2050 by phasing out coal, accelerating the shift to EVs, and by ending and reversing deforestation. Over 130 countries have pledged to reach net-zero emissions by mid-century. The most recent COP-27, held in Sharm El-Sheikh, Egypt, reaffirmed commitments to limit global temperature rise to 1.5°C (2.7°F). Additional outcomes included the launch of the Forest and Climate Leaders' Partnership to end forest loss by 2030, and an agreement to create a loss and damage fund to provide financial assistance to developing countries that are vulnerable to climate change (UNFCCC 2022b).
- **Montreal Protocol.** The Montreal Protocol is an international agreement, adopted in September 1987, to limit the production and use of ozone-depleting substances (ODS), such as hydrochlorofluorocarbons (HCFCs) and chlorofluorocarbons (CFCs) that are used in refrigeration and air-cooling systems. The treaty received universal ratification and it is estimated that the Parties of the Protocol have reduced the use of ODS by 98 percent compared to 1990 levels. The Kigali Amendment added HFCs to the list of identified substances to phase down starting in 2016. HFCs were initially used to replace ODS, but their high GWP led the parties to add HFCs to the list of controlled substances, with the goal of reducing their use by over 80 percent by the late 2040s (UN 2023b). The amendment is expected to avoid more than 80 billion metric tons of CO<sub>2</sub>e by 2050—equivalent to 0.5°C of warming by 2100 (EPA 2022p).
- **Global Methane Pledge.** On November 2, 2021, more than 100 countries representing 70 percent of the global economy and nearly half of anthropogenic CH<sub>4</sub> emissions signed a pledge to reduce global CH<sub>4</sub> emissions to help limit warming to 1.5°C (2.7°F) (EU 2021). The Global Methane Pledge

spans both developing and developed nations and commits to a reduction in global CH<sub>4</sub> levels reaching at least 30 percent reduction from 2020 levels by 2030. If the plans of the Pledge are met, warming could be reduced by at least 0.2°C (0.36°F) by 2050, providing a significant basis for global emissions reduction and climate mitigation efforts (U.S. White House 2021). The Global Methane Pledge also provides co-benefits for improved air quality, mitigation of health issues, and reduction of agricultural losses. As of November 2022, 150 countries have endorsed the Global Methane Pledge, and the United States, EU, and 11 additional countries finalized the Global Methane Pledge Energy Pathway with detailed steps on how to accelerate CH<sub>4</sub> emissions reductions, specifically in the fossil fuel sector (U.S. State Department 2022).

- **The EU GHG Emissions Trading System.** In January 2005, the EU Emissions Trading System commenced operation as the largest multicountry, multisector GHG emissions trading system worldwide (EU 2018). The aim of the system is to help EU member states achieve compliance with their commitments under first the Kyoto Protocol and now the Paris Agreement (EU 2015). This trading system does not entail new environmental targets; instead, it allows for less expensive compliance with existing targets. The scheme is based on Directive 2003/87/EC, which entered into force on October 25, 2003 (EU 2015) and covers about 10,000 energy-intensive installations across the EU. This represents 40 percent of Europe’s emissions of CO<sub>2</sub> (EU 2018). These installations include commercial aviation, combustion plants, oil refineries, iron and steel plants, and factories making cement, glass, lime, brick, ceramics, pulp, and paper (EU 2018). To achieve climate neutrality in the EU by 2050, the EU Emissions Trading System is under review with the aim to expand the scope of coverage, but also update its target by reducing GHGs to at least 55 percent below 1990 levels by 2030 (EU 2020). Installations covered by the Emissions Trading System reduced emissions by about 35 percent between 2005 and 2019 (EU no date). The Emissions Trading System was updated under the Phase 4 Revision in 2021 to enact new measures in order to meet the 2030 goal of reducing net emissions by at least 55 percent, including setting up new funds to support low-carbon power and more targeted rules on carbon leakage (European Commission 2023).
- **Fuel Economy Standards in Asia.** Both Japan and China have taken actions to reduce fuel use, CO<sub>2</sub> emissions, and criteria pollutant emissions from vehicles. Japan has invested heavily in research and development programs to advance fuel-saving technologies, has implemented fiscal incentives such as high fuel taxes and differential vehicle fees, and has mandated fuel economy standards based on vehicle weight class (using country-specific testing procedures [Japan 1015/JC08]). In 2015, Japan’s Ministry of Land, Infrastructure, Transport, and Tourism finalized new fuel economy standards for light and medium commercial vehicles sold in 2022 that are a 23 percent increase from the 2015 prevailing standard (International Council on Clean Transportation [ICCT] 2015). Similarly, China has implemented fuel economy standards, based on the Worldwide Harmonized Light-duty Test Cycle instead of the previously used New European Driving Cycle. In December 2019, China set new standards for passenger vehicles produced or imported to an average target of 59 mpg. In June 2019, Japan issued new standards that require the average fleet fuel economy in 2030 to be above 60 mpg (Yang and Rutherford 2019).
- **China EV Targets.** China has established a program that effectively sets quotas for plug-in electric vehicles (PEVs) and fuel cell electric vehicles, under which PEVs and fuel cell electric vehicles were expected to make up at least 10 percent of each automaker’s sales in China in 2019, and 12 percent in 2020 (ICCT 2021). Subsequent targets under Phase 2 of this policy will require these vehicles to make up 18 percent of total sales by 2023. China has not yet set a timetable to reach 100 percent EV sales but is expected to join other nations in phasing out sales of ICE vehicles by 2040.

- **Other International GHG Mitigation Efforts.** There are many nations adopting other national actions, such as cap-and-trade programs, to reduce GHG vehicle emissions. Some efforts from large emitters include:
  - In January 2021, China launched its new national emissions trading scheme, which allows market emitters to buy, sell, and trade emissions credits (International Carbon Action Partnership [ICAP] 2021). These new plans build upon existing cap-and-trade efforts launched in December 2017. The updates include goals of a reduction in carbon emissions per unit of gross domestic product by 18 percent compared to the 2020 levels within the next 5 years, a peak of emissions before 2030, and carbon neutrality by 2060 (ICAP 2021).
  - Officially launched in 2017, India currently has a similar cap-and-trade program, which has been cited as the first program to include PM aerosols within its emissions trading scheme program (University of Chicago 2019). As of 2019, India has also pledged to reduce emissions intensity by 33 to 35 percent compared to 2005 levels (Timperley 2019).

To date, many other countries have adopted a national cap-and-trade program including, but not limited to, Mexico, Australia, Colombia, Chile, New Zealand, South Korea, Japan, and nearly all the nations in the EU (Plumber and Popovich 2019).

#### **E.4.3.5 Reference Case Modeling Runs**

The modeling runs and sensitivity analysis simulate relative changes in atmospheric CO<sub>2</sub> concentrations, global mean surface temperature, precipitation, sea-level rise, and ocean pH that could result under each alternative. The modeling runs are based on the reductions in emissions estimated to result from each of the action alternatives compared to projected emissions under the relevant No-Action Alternative. They assume a climate sensitivity of 3°C (5.4°F) for a doubling of CO<sub>2</sub> concentrations in the atmosphere.<sup>52</sup> The approach uses the following five steps to estimate these changes.

1. NHTSA assumed that global emissions under the relevant No-Action Alternative would follow the trajectory provided by the global emissions scenario.
2. NHTSA assumed that global emissions for each action alternative would be equal to the global emissions under the relevant No-Action Alternative minus the reductions in emissions of CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, SO<sub>2</sub>, NO<sub>x</sub>, CO, and VOCs estimated to result from each action alternative. For example, the global emissions scenario under Alternative PC2LT4 and Alternative HDPUV10<sup>53</sup> equals the global emissions scenario minus the emissions reductions from those alternatives.
3. NHTSA used MAGICC7 to estimate the changes in global CO<sub>2</sub> concentrations and global mean surface temperature through 2100 using the global emissions scenario under each alternative developed in Steps 1 and 2.
4. NHTSA utilized the CO2SYS model to estimate changes in ocean pH. Changes in global CO<sub>2</sub> concentrations calculated within the MAGICC7 model are parsed to the CO2SYS ocean pH model to

---

<sup>52</sup> NHTSA used a climate sensitivity of 3°C (5.4°F), as this is IPCC's best estimate, with a *likely* range of 1.5 to 4.0°C (2.7 to 7.2°F) (IPCC 2021a).

<sup>53</sup> Alternatives PC2LT4 and HDPUV10 are NHTSA's Preferred Alternatives under the CAFE standards and HDPUV FE standards, respectively. Alternative PC2LT4 represents a 2 percent increase per year, year over year for MYs 2027–2032 passenger cars, and 4 percent increase per year, year over year for MYs 2027–2032 light trucks. Alternative HDPUV10 represents a 10 percent increase per year, year over year for MYs 2030–2035 HDPUVs. For more information on the action alternatives and methodology, see Chapter 2, Sections 2.2.2.1, *CAFE Standard Action Alternatives*, and 2.2.2.2, *HDPUV FE Standard Action Alternatives*.

calculate change. This model uses two of four measurable parameters of the ocean CO<sub>2</sub> system—total alkalinity, total inorganic CO<sub>2</sub>, pH, and either fugacity or partial pressure of CO<sub>2</sub>—to calculate the remaining two input parameters. NHTSA used the CO2SYS model to estimate the pH of ocean water in the years 2040, 2060, and 2100 under the relevant No-Action Alternative and each of the action alternatives.

5. NHTSA used the increase in global mean surface temperature to estimate the increase in both global average precipitation and sea-level rise for each alternative using the global emissions scenario.

#### **E.4.3.6 Sensitivity Analysis**

NHTSA performed a sensitivity analysis to examine the effect of various equilibrium climate sensitivities on the results, using MAGICC7 to run the same probabilistic distribution as in IPCC WGI AR6 for the categorization and climate assessment of the SSP scenarios. Equilibrium climate sensitivity is the projected responsiveness of Earth's global climate system to increased ERF from higher GHG concentrations and is expressed in terms of changes to global surface temperature resulting from a doubling of CO<sub>2</sub> compared to preindustrial atmospheric concentrations (278 ppm CO<sub>2</sub>) (IPCC 2021a). Sensitivity analyses examine the relationship among the alternatives, likely climate sensitivities, and scenarios of global emissions paths and the associated direct and indirect impacts for each combination.

The best estimate from IPCC WGI AR6 probabilistic output expresses stronger confidence in some fundamental processes in models that determine climate sensitivity than the AR5 (IPCC 2021a). According to IPCC, the very likely range of equilibrium climate sensitivity is between 2°C (3.6°F) (*high confidence*) and 5°C (9°F) (*medium confidence*). The assessed best estimate is 3°C (5.4°F) with a *likely* range of 2.5°C (4.5°F) to 4°C (7.2°F) (*high confidence*), compared to 1.5°C (2.7°F) to 4.5°C (8.1°F) in AR5.

NHTSA assessed climate sensitivities of 1.9, 3.0, and 4.8°C (3.4, 5.4, and 8.6°F) for a doubling of CO<sub>2</sub> concentrations in the atmosphere. NHTSA performed the sensitivity analysis around three of the alternatives—the No-Action Alternative, Alternative PC1LT3, and Alternative PC6LT8—because this was deemed sufficient to assess the effect of various climate sensitivities on the results under the range of alternatives considered in this EIS. The best estimate derived from the median output from MAGICC is in line with this climate sensitivity.

The approach uses the following four steps to estimate the sensitivity of the results to alternative estimates of the climate sensitivity.

1. NHTSA used the SSP3-7.0 scenario to represent emissions from the No-Action Alternative.
2. Starting with the respective scenarios, NHTSA assumed reductions in global emissions of CO<sub>2</sub>, CH<sub>4</sub>, N<sub>2</sub>O, SO<sub>2</sub>, NO<sub>x</sub>, CO, and VOCs for both the CAFE alternatives and the HDPUV FE alternatives. For the CAFE alternatives, NHTSA assessed emissions resulting from the least stringent alternative (Alternative PC1LT3) would be equal to the global emissions of each pollutant under the No-Action Alternative minus emissions of each pollutant under Alternative PC1LT3. Separately, NHTSA used the same approach for Alternative PC6LT8 (the lowest GHG emissions alternative) compared to the No-Action Alternative.<sup>54</sup> The same assessment was done for HDPUVs using Alternative HDPUV4

---

<sup>54</sup> Some SO<sub>2</sub> emissions are associated with charging EVs. However, total power plant emissions are limited by caps under the EPA Acid Rain Program and the Cross-State Air Pollution Rule, and will be reduced through emissions standards such as the Mercury and Air Toxics Standards rule. Because of these rules and advances in technology, emissions from the power-generation sector are expected to decline over time (i.e., the grid is expected to become cleaner). Any economic activity or

(least stringent) and Alternative HDPUV14 (most stringent). All SO<sub>2</sub> reductions were applied to Aerosol Region 1 of MAGICC, which includes North America.

3. NHTSA assumed a range of climate sensitivity values consistent with the 5th, 50th, to 95th percentile of the probability distribution from the IPCC WGI AR6 (IPCC 2021a), in line with a climate sensitivity of 1.9°C (compared to the IPCC estimate of 2.0°C), 3.0°C, and 4.8°C (compared to the IPCC estimate of 5.0°C), respectively.
4. For each climate sensitivity value in Step 3, NHTSA used MAGICC7 to estimate the resulting changes in CO<sub>2</sub> concentrations and global mean surface temperature, as well as the regression-based analysis to estimate sea-level rise through 2100 for the global emissions scenarios in Steps 1 and 2.

Chapter 5, Section 5.4, *Environmental Consequences*, presents the results of the model runs for the alternatives. For the direct and indirect impacts analysis, the sensitivity analysis was performed against the SSP3-7.0 scenario (800 ppm in 2100).

For the cumulative impacts analysis, the sensitivity analysis also assesses the sensitivity around different global emissions scenarios. NHTSA assumed multiple global emissions scenarios, including SSP2-4.5 (568 ppm in 2100), SSP1-2.6 (438 ppm in 2100), and SSP3-7.0 (800 ppm in 2100).

## E.5 Health, Societal, and Environmental Impacts of Climate Change

### E.5.1 Introduction

This section discusses how climate change resulting from global GHG emissions (including U.S. LD vehicles and HDPUVs under the Proposed Action and alternatives) could affect certain key natural and human resources: freshwater resources; terrestrial and freshwater ecosystems; ocean systems, coasts, and low-lying areas; food, fiber, and forest products; urban areas; rural areas; human health; human security; and stratospheric ozone. In addition, this section discusses compound events, tipping points, and abrupt climate change. Regional impacts of climate change are discussed in Chapter 5, Section 5.4.3.3, *Regional Impacts of Climate Change*.

### E.5.2 Sectoral Impacts of Climate Change

NHTSA's analysis of sectoral impacts of climate change draws largely from recent studies and reports, including the IPCC AR6 (IPCC 2021a, 2021b, 2022a), the IPCC *Special Study: Global Warming of 1.5° C* (IPCC 2018), the IPCC *Special Report on the Ocean and Cryosphere in a Changing Climate* (IPCC 2019a), the IPCC *Special Report on Climate Change, Desertification, Land Degradation, Sustainable Land Management, Food Security, and Greenhouse Gas Fluxes in Terrestrial Ecosystems* (IPCC 2019b), and the GCRP NCA4 (GCRP 2017, 2018a). The IPCC and GCRP reports, in particular, provide a comprehensive overview of the state of scientific, technical, and socioeconomic knowledge on climate change, its causes, and its potential impacts. To reflect the likelihood of climate change impacts accurately for each sector, NHTSA references and uses the IPCC uncertainty guidelines (Section E.1.1, *Uncertainty in the IPCC Framework*). This approach provides a consistent method to define confidence levels and percent probability of a projected outcome or impact. This is primarily applied for key IPCC and GCRP findings

---

trend that leads to an increase in electrical demand—including increases in EV sales and use—would be accommodated by the power industry in planning for compliance with applicable emissions limitations.

where IPCC or GCRP has defined the associated uncertainty with the finding (other sources generally do not provide enough information or expert consensus to elicit uncertainty rankings).

Recent reports from GCRP and such agencies as the NRC are also referenced in this chapter. NHTSA relies on major international or national scientific assessment reports because these reports have assessed numerous individual studies to draw general conclusions about the potential impacts of climate change. This material has been well vetted, both by the climate change research community and by the U.S. government. In addition, NHTSA has supplemented the findings from these reports with recent peer-reviewed information, as appropriate.

### **E.5.2.1 Freshwater Resources**

This section provides an overview of the recent findings regarding observed and projected impacts of climate change on freshwater resources in the United States and globally. More than 70 percent of the surface of the Earth is covered by water, but only 2.5 percent is fresh water. Respectively, freshwater contributions include permanent snow cover in the Antarctic, the Arctic, and mountainous regions (68.7 percent); groundwater (29.9 percent); and fresh water in lakes, reservoirs, and river systems (0.26 percent) (UNESCO 2006).

Potential risks to freshwater resources are expected to increase with increasing GHG emissions; for example, higher emissions are projected to result in less renewable water at the same time as continued population growth (IPCC 2021a). Although some positive impacts are anticipated, including reductions in water stress in some areas because of increased runoff and increased primary productivity in some systems, such as boreal waters, the negative impacts are expected to outweigh positive impacts (IPCC 2022a; GCRP 2018a).

#### **Observed and Projected Climate Impacts**

In recent decades, annual average precipitation increases have been observed across the Midwest, Great Plains, Northeast, and Alaska, while decreases have been observed in Hawaii, the Southeast and the Southwest (GCRP 2017; Walsh et al. 2014; Huang et al. 2017). Nationally, there has been an increase of 4 percent in annual precipitation over the period from 1901 to 2016 (GCRP 2017). According to GCRP, globally, for mid-latitude land areas of the Northern Hemisphere, annual average precipitation has *likely* increased since 1901 (GCRP 2017), with evidence of a faster increase since the 1980s (*medium confidence*) (IPCC 2022a). For most other latitudinal zones, long-term trends in average precipitation are uncertain due to data quality, data completeness, or disagreement among available estimates (IPCC 2022a). Globally, average precipitation over land areas has likely increased since the 1950s (*medium confidence*), but with large interannual variability and regional heterogeneity (IPCC 2021a).

Anthropogenic climate change has altered annual mean streamflow trends around the world, with some regions like eastern Asia and western North America showing decreasing trends, and other regions like northern Asia and eastern North America showing increasing trends, between 1950s and 2010s (IPCC 2022a). Globally, in regions with seasonal snow storage, warming has led to earlier occurrence of the maximum streamflows from snowmelt during the spring and increased winter streamflows because more winter precipitation falls as rain instead of snow (IPCC 2022a citing Dudley et al. 2017, Bonsal et al. 2020, and Fox-Kemper et al. 2021). These reduced snow-to-rain ratios are leading to significant differences between the timing of water supply and demand (*medium confidence*). In particular, warming temperatures and reduced snowpack are decreasing surface water and groundwater availability in much of the western United States (U.S. Bureau of Reclamation 2021). Changes in the

timing of flows and temperatures of freshwater bodies *likely* affect local wildlife populations through phenological and distribution/range shifts (*high confidence*) (GCRP 2018a). Average global precipitation is projected to increase over the next century; generally, wet places are expected to get wetter and dry places are expected to get drier (IPCC 2021a).

The frequency and intensity of heavy precipitation events have been increasing across most of the United States (U.S. Bureau of Reclamation 2011; GCRP 2017). According to GCRP (2017) NCA4, river floods have been increasing in parts of the central United States, but overall, there are no detectable changes in observed flooding magnitude, duration, or frequency in the United States. Globally, anthropogenic climate change has increased the likelihood of extreme precipitation and associated increase in the frequency and magnitude of river floods (*high confidence*) (IPCC 2022a). Projections reveal high regional variations, with intensification of heavy precipitation and flooding for Africa and Asia (*high confidence*), North America (*medium to high confidence*), and Europe (*medium confidence*) for 1.5°C (2.7°F) of warming (IPCC 2021b).

The quality of freshwater resources may be adversely affected by the projected changes in frequency and magnitude of extreme precipitation events and associated floods. Locally variable changes in precipitation and increases in high flow events can affect the transport of pollutants, sediments, nutrients, and microbial pathogens to freshwater bodies, which can have cascading impacts on water supplies, water quality, treatment costs, public health, and ecosystems (GCRP 2018a). Coastal floods related to sea-level rise and the resulting increase in storm surge height could also result in increased inland impacts such as saltwater intrusion into coastal rivers and aquifers, which could threaten drinking water supplies, infrastructure, and the health of coastal and estuarine ecosystems (GCRP 2017, 2018a).

The risk faced from heavy precipitation and flooding events is compounded by aging water infrastructure such as dams and levees across the United States. The scope of the nation's exposure to this risk has not yet been fully identified; however, the estimated reconstruction and maintenance costs for the totality of American water infrastructure is estimated in the trillions of dollars (GCRP 2018a). It can be said with *high confidence* that extreme precipitation events are projected to increase in a warming climate, and that deteriorating water infrastructure compounds the risk climate change poses to society (*high confidence*).

In the United States, there is mixed information on the historical connection between climate change and drought. GCRP found that there is little evidence of a human influence on past precipitation shortages (i.e., meteorological or hydrological droughts); however, there is *high confidence* of a human influence on surface soil moisture deficits due to higher temperatures and the resultant increase in evapotranspiration (i.e., agricultural droughts) (GCRP 2017). This increased evapotranspiration has also increased the need for human use of water in many areas. Over the past 3 decades, efficiency gains in irrigation methods have generally kept pace with this increased usage; however, without further improvements in this area, future human demand could outpace supply in many regions (GCRP 2018a). In fact, due to limitations on surface water storage and trading of water across basins and usages, certain U.S. aquifers have experienced significant depletion (GCRP 2018a citing Russo and Lall 2017). Globally, increasing trends in agricultural droughts are more evident than increasing trends in meteorological droughts in several regions of the world (IPCC 2022a citing Douville et al. 2021 and Seneviratne et al. 2021), with varying degrees of confidence on attribution to anthropogenic climate change. For example, there is *high confidence* in anthropogenic influence on increased meteorological droughts in southwestern Australia but *low confidence* in central Africa (IPCC 2022a). Drought hazards

are projected to be less severe at 1.5°C (2.7°F) of warming compared to 2°C (3.6°F) (IPCC 2018 citing Smirnov et al. 2016, Sun et al. 2017, Arnell et al. 2018, and Liu et al. 2018; IPCC 2019b).

Dry spells are also projected to increase in length in most regions, especially in the southern and northwestern portions of the contiguous United States (EPA 2015d). Projected changes in total average annual precipitation are generally small in many areas, but both wet and dry extremes (heavy precipitation events and length of dry spells) are projected to increase substantially almost everywhere. Long-term (multi-seasonal) drought conditions are also projected to increase in parts of the Southwest (GCRP 2017). Furthermore, trends of earlier spring melt and reduced snow water equivalent are expected to continue, and analyses using higher emissions scenarios project with *high confidence* that the western United States will see chronic, long-duration hydrological droughts (GCRP 2017).

Rising temperatures across the United States have reduced total snowfall, lake ice, seasonal snow cover, sea ice, glaciers, and permafrost over the last few decades (GCRP 2017; EPA 2016e citing Mote and Sharp 2016). The impact of climate change on groundwater recharge varies globally (IPCC 2022a citing Thomas et al. 2016, Asoka et al. 2018, Vincent et al. 2019, and Nygren et al. 2020). There is *medium confidence* that increased precipitation intensities have enhanced groundwater recharge, particularly in the tropics, while there is *high confidence* that groundwater depletion has occurred over at least the 21st century due to water extraction for irrigation within many agricultural areas (IPCC 2021a). Both globally and in the United States, sea-level rise, storms and storm surges, and changes in surface water and groundwater use patterns are expected to compromise the sustainability of coastal freshwater aquifers and wetlands (U.S. Bureau of Reclamation 2016; GCRP 2017). These effects are of particular concern in Hawaii and U.S. territories in the Caribbean and Pacific, threatening previously dependable and safe water supplies. The freshwater supplies in these same areas also face increased potential for contamination from increasingly frequent extreme weather events that damage freshwater infrastructure (GCRP 2018a).

Globally, most observed changes of water quality attributed to climate change are known from isolated, short-term studies, mostly of rivers or lakes in high-income countries. The most frequently reported change is more intense eutrophication (i.e., an increase in phosphorus and nitrogen in freshwater resources) and algal blooms (i.e., excessive growth of algae) at higher temperatures, or shorter hydraulic retention times and higher nutrient loads resulting from increased storm runoff. Changes in the amount of water flow in surface water bodies due to climate change presents chronic problems, such as increased cost of water treatment and greater risk to public health due to pollutant concentrations (GCRP 2018a). While extreme floods cause massive physical disturbance, moderate floods may have some positive effects, such as providing woody debris that contributes to habitat complexity and diversity, flushing fine sediments and nutrients from lakes and estuaries which may reduce the risk of eutrophication (IPCC 2022a citing Peters et al. 2016 and Talbot et al. 2018). For rivers, all reported impacts on water quality are negative, and surface water quality as a whole declines as water temperature increases (*high confidence*) (GCRP 2018a). Water shortages and droughts have been associated with diarrheal disease peaks (IPCC 2022a, citing Epstein et al. 2020, Subiros et al. 2019, and Boithias et al. 2016). Additionally, droughts can reduce groundwater levels, increasing the risk of groundwater contamination and creating challenges for management and drinking water treatment (IPCC 2022a citing Kløve et al. 2014 and Khan et al. 2015).

Changes in sediment transport are expected to vary regionally and by land-use type, with potentially large increases in some areas, resulting in alterations to reservoir storage and river channels, affecting flooding, navigation, water supply, and dredging (GCRP 2018a; IPCC 2022a).

## **Adaptation**

Given the uncertainty associated with climate change, adaptation planning often involves anticipatory scenario-based planning and the identification of flexible, low-regrets strategies (e.g., water conservation and demand-side management) to maximize resilience. In the United States and globally, current and projected impacts of climate change on water resources have sparked several responses by water resource managers. In 2011, Federal agencies, which manage most of the freshwater resources in the United States, worked with stakeholders to develop a National Action Plan for managing freshwater resources in a changing climate to help ensure adequate freshwater supplies, while also protecting water quality, human health, property, and aquatic ecosystems (ICCATF 2011). Water utilities are determining ways to adjust planning, operational, and capital infrastructure strategies (EPA 2015e; Abt Associates 2016). Water conservation and demand management are also being promoted as important nonstructural, low-regrets<sup>55</sup> approaches for managing water supply. Investing in ecosystem protection and restoration and other nature-based solutions have also been identified as adaptation priorities to build resilience in the water sector (EPA 2022q).

However, NCA4 states that management of surface water and groundwater sources across Federal agencies has been hampered by a lack of coordination, creating inefficiencies in the response to climate change. Climate change mitigation policies, if not designed with careful attention to water resources, could increase the magnitude, spatial coverage, and frequency of water deficits given potential increased demand for irrigation water for bioenergy crops (Hejazia et al. 2015).

### **E.5.2.2 Terrestrial and Freshwater Ecosystems**

This section provides an overview of the recent findings regarding observed and projected impacts of climate change on the terrestrial and freshwater ecosystems in the United States and globally. Ecosystems include all living organisms and their environs that interact as part of a system (GCRP 2018a). These systems are often delicately balanced and sensitive to internal and external pressures due to both human and nonhuman influences. Ecosystems are of concern to society because they provide beneficial ecosystem services such as jobs (e.g., from fisheries and forestry), fertile soils, clean air and water, recreation, and aesthetic value (GCRP 2018a citing Millennium Ecosystem Assessment 2005). Terrestrial and freshwater ecosystems in the United States and around the world are experiencing rapid and observable changes. The ecosystems addressed in this section include terrestrial ecosystems, such as forests, grasslands, shrublands, savanna, and tundra; aquatic ecosystems, such as rivers, lakes, and ponds; and freshwater wetlands, such as marshes, swamps, and bogs.

#### **Observed and Projected Climate Impacts**

The impacts of climate change on terrestrial and freshwater ecosystems have been observed at a variety of scales, including individuals (e.g., changes in genetics and physical characteristics), populations (e.g., changes in timing of life-cycle events), and species (e.g., changes in geographic range) (GCRP 2018a citing Scheffers et al. 2016). Several reviews of climate change impacts on ecosystem services indicate that 59 to 82 percent of ecosystem services have experienced impacts from climate change (Runting et al. 2016; Scheffers et al. 2016).

---

<sup>55</sup> A low-regrets approach is commonly used to signify a method of action with relatively low cost and relatively large benefits under predicted future climates.

Recent global satellite and ground-based data have identified phenology<sup>56</sup> shifts, including earlier spring events such as breeding, budding, flowering, and migration, which have been observed in hundreds of plant and animal species (EPA 2021j; IPCC 2022a citing Cook et al. 2012, Cohen et al. 2018, Piao et al. 2019, and Menzel et al. 2020). Migratory species that rely on one primary food source are particularly vulnerable to climate change due to phenological mismatch (GCRP 2018a citing Both et al. 2010, Mayor et al. 2017, and Ohlberger et al. 2014). In the United States, modeled trends in timing of first leaf and bloom events, using 1981 to 2010 as a baseline, show that these are happening earlier in the year throughout the northern and western regions, but later in much of the southern regions (EPA 2016e citing Schwartz et al. 2013). Phenological mismatches that result in unfavorable breeding conditions could cause significant negative impacts on species' breeding processes (GCRP 2018a citing Miller-Rushing et al. 2010, and Mayor et al. 2017; Little et al. 2017 citing McNab 2010 and Potti 2008; Pecl et al. 2017 citing CAFF 2013 and Mustonen 2015). In some ecosystems, higher trophic levels may be more sensitive to climate change than lower trophic levels, which can affect energy demands and mortality rates of prey, affect overall ecosystem functioning, and alter energy and nutrient flow (GCRP 2018a citing Laws and Joern 2013, McCluney and Sabo 2016, Verdeny-Vilalta and Moya-Laraño 2014, Miller et al. 2014, and Zander et al. 2017).

Species respond to stressors such as climate change by phenotypic<sup>57</sup> or genotypic<sup>58</sup> modifications, migrations, or extinction (IPCC 2022a citing Menzel et al. 2020, Román-Palacios and Wiens 2020, and Weeks et al. 2020). Changes in morphology<sup>59</sup> and reproductive rates have been attributed to climate change. For example, the egg sizes of some bird species are changing with increasing regional temperatures (Potti 2008). At least one study indicates that birds in North America are experiencing decreased body size due to changes in climate (Van Buskirk et al. 2010).

Over the past several decades, a pole-ward (in latitude) and upward (in elevation) extension of various species' ranges has been observed that may be attributable to increases in temperature (GCRP 2018a; IPCC 2022a). Climate change has led to range contractions in almost half of studied terrestrial animals and plants in North America (GCRP 2018a citing Wiens 2016). It is estimated that terrestrial animal communities have shifted ranges at an average of 3.8 miles per decade, with marine communities recording even larger range shifts of up to 17.4 miles per decade over the last century (GCRP 2018a citing Parmesan and Yohe 2003, Burrows et al. 2011, and Walsh et al. 2015). Climate-driven range shifts, along with disturbances such as introduction of invasive species, may result in significant changes in ecosystem composition and new species interactions, creating entirely new ecological communities with no historical analogs (GCRP 2018a citing Williams and Jackson 2007 and Blois et al. 2013). A recent study suggests that species redistribution is linked to reduced terrestrial productivity, impacts on marine community assembly, and threats to the health of freshwater systems from toxic algal blooms (Pecl et al. 2017).

IPCC indicates that 20 to 30 percent of species assessed so far are likely to be at an increased risk of extinction, if global average warming exceeds 1.5 to 2.5°C (2.7 to 4.5°F) (*medium confidence*). Even the lowest estimates of species extinction are 1,000 times the natural background rates (IPCC 2022a). A recent study suggests that local extinctions related to climate change are already widespread, with 47

---

<sup>56</sup> *Phenology* refers to the relative timing of species' life-cycle events.

<sup>57</sup> Referring to an organism's observable traits, such as color or size.

<sup>58</sup> Referring to an organism's genetic makeup.

<sup>59</sup> Referring to an organism's structural or anatomical features (e.g., egg size, wing shape, or even of the organism as a whole).

percent of 976 species reviewed having experienced climate-related local extinctions (Wiens 2016). Regional warming puts some bird populations at risk when increased predatory populations or declines in available habitat (resulting in fewer appropriate nesting and egg-laying spots) leads to increased vulnerability of their eggs to predators (Wormworth and Mallon 2010).

Additionally, an increase in phosphorus and nitrogen in freshwater resources (eutrophication) from increased agricultural runoff is probable, especially in areas that experience heavier or more frequent precipitation events (GCRP 2018a citing Ficklin et al. 2013, Sinha et al. 2017, Fant et al. 2017, and Johnson et al. 2015). The effects of eutrophication include excessive growth of algae (algal blooms), which reduce dissolved oxygen in the water, causing some plants, fish, and invertebrates to die.

Climate change may result in more uniform population structures, leading to increased competition and potentially resulting in extinctions (GCRP 2018a citing Ohlberger et al. 2014 and Lancaster et al. 2017). For example, extreme weather events can benefit invasive species by decreasing native communities' resistance and by occasionally putting native species at a competitive disadvantage (GCRP 2018a citing Diez et al. 2012, Kats et al. 2013, Tinsley et al. 2015, and Wolf et al. 2016).

Diverse observations suggest that global terrestrial primary production increased over the latter 20th and early 21st centuries due to a combination of the fertilizing effect of increasing atmospheric CO<sub>2</sub>, nutrient additions from human activities, longer growing seasons, and forest regrowth (GCRP 2018a citing Campbell et al. 2017, Graven et al. 2013, Wenzel et al. 2016, Zhu et al. 2016, and Domke et al. 2018). Conversely, in areas experiencing drought (such as in Western North America), water stress results in decreased tree growth and increased tree mortality (IPCC 2022a). A more intense hydrological cycle, including more frequent droughts, may reduce photosynthesis and, therefore, reduce ecosystem productivity and carbon storage (GCRP 2017). Alternatively, as plants gain more biomass, their net storage of carbon might be limited by nutrient availability in soils (Finzi et al. 2011).

Elevated CO<sub>2</sub> concentrations have physiological impacts on plants, which can result in changes in both plant water utilization and local climate. A process referred to as CO<sub>2</sub>-physiological forcing (Cao et al. 2010) occurs when increased CO<sub>2</sub> levels cause plant stomata (pores in plant leaves, which allow gas exchange of CO<sub>2</sub> and water vapor) to open less widely, resulting in decreased plant transpiration (Cao et al. 2010). Reduced stomata opening increases water use efficiency in some plants, which can increase soil moisture content, mitigating drought conditions (McGrath and Lobell 2013 citing Ainsworth and Rogers 2007, Leakey 2009, Hunsaker et al. 2000, Conley et al. 2001, Leakey et al. 2004 and 2006, and Bernacchi et al. 2007; IPCC 2022a). Reduced plant transpiration can also cause a decrease in evapotranspiration, which may trigger adjustments in water vapor, clouds, and surface radiative fluxes. These adjustments could ultimately drive macroclimatic changes in temperature and the water cycle (Cao et al. 2010). However, the estimation of large-scale transpiration response to increased CO<sub>2</sub>, based on leaf-level responses of water-use efficiency is understood to be complex, owing to competing forces (Tor-ngern et al. 2014; IPCC 2022a citing Bernacchi and VanLoocke 2015 and Tor-ngern et al. 2015). Elevated CO<sub>2</sub> concentrations may also affect soil microbial growth rates and their impact on terrestrial carbon pools; however, these effects are complex and not well understood (Wieder et al. 2014; Bradford et al. 2016).

Ecological tipping points<sup>60</sup> begin with initial changes in a biological system (e.g., introduction of a new predatory animal species to the system due to changes in climate that are favorable to the newly

---

<sup>60</sup> An ecological tipping point is described by IPCC (2014), in reference to the potential for Amazonian ecosystem shifts, as “a large-scale, climate-driven, self-reinforcing transition” of one ecosystem into another type.

introduced species), which are then amplified by positive feedback loops and can lead to cascading effects throughout the system. The point at which the system can no longer retain stability is a threshold known as a tipping point. Changes in such situations are often long-lasting and hard to roll back; managing these conditions is often very difficult (IPCC 2022a citing Prober et al. 2019, Berdugo et al. 2020, and Bergstorm et al. 2021). Leadley et al. (2010) evaluated the potential tipping point mechanisms and their impacts on biodiversity and ecosystem services for several ecosystems. Examples include warming tundra that will reduce albedo, providing a warming feedback that will result in further thawing of tundra; and the large-scale changes of Amazonian rainforests to agricultural lands, resulting in decreased local and regional rains, promoting further decline of trees.

Forest ecosystems and services are at risk of greater fire disturbance when they are exposed to increased warming and drying, as well as declines in productivity and increases in insect disturbances (e.g., pine beetles). Boreal fire regimes have become more intense in terms of areas burned, length of fire season, and hotter, more energetic fires (IPCC 2022a citing Hanes et al. 2019, Veraverbeke et al. 2021, and Scholten et al. 2021). Cascading effects in forests are possible when fire-related changes in forest composition result in reduced capacity as a carbon sink and reduced albedo, or when post-fire increases in soil erosion contribute to indirect carbon emissions, all of which factor into further warming, putting forests at even greater risk of fire and dieback (IPCC 2022a citing Rogers et al. 2015, Chen et al. 2017, and van der Werf et al. 2017).

Limiting warming to 1.5°C (2.7°F) compared to 2°C (3.6°F) may benefit terrestrial and wetland ecosystems through avoidance or reduction of changes, such as biome transformation, species range losses, and increased extinction risks (all *high confidence*) (IPCC 2018 citing Hoegh-Guldberg et al. 2018).

### **Adaptation**

In the context of natural resource management, climate-driven changes in ecosystems are most effectively managed through highly adaptive and proactive approaches that address emerging and anticipated impacts of climate change (GCRP 2018a). The ability or inability of ecosystems to adapt to change is referred to as adaptive capacity. There could be notable regional differences in the adaptive capacity of ecosystems, and adaptive capacity is moderated by anthropogenic influences and capabilities. The ultimate impact of climate change on ecosystems depends on the speed and extent to which these systems can adapt to a changing climate. Rapid rather than gradual climate change may put populations at risk of extinction before beneficial genes are able to enhance the fitness of the population and its ability to adapt (Staudinger et al. 2013 citing Hoffmann and Sgro 2011).

Some adaptation strategies include landscape-scale and ecosystem-based conservation and management approaches, increasing habitat connectivity, manipulating habitat, conserving populations with more genetic diversity or behaviors, sourcing seeds, assisting relocation or migration, and engaging in offsite conservation (e.g., seed banking and captive breeding) (GCRP 2018a). EPA (2016f) stresses the enhancement of natural buffers to protect and help ecosystems increase adaptive capacity. Anthropogenic stressors can compound climate change impacts, so reducing these effects, such as nutrient pollution or invasive species introduction, can bolster resilience (NPS 2016, 2021). The NCA4 report indicates the effectiveness of existing adaptation strategies and approaches may be significantly reduced in the face of a changing climate (GCRP 2018a).

### E.5.2.3 Ocean Systems, Coasts, and Low-Lying Areas

This section provides an overview of recent findings regarding observed and projected impacts of climate change on ocean systems, coasts, and low-lying areas in the United States and globally. Ocean systems cover approximately 71 percent of the Earth's surface and include many habitats that are vital for coastal economies. Coastal systems and low-lying areas include all areas near the mean sea level. Coastal systems consist of both natural systems (i.e., rocky coasts, beaches, barriers, sand dunes, estuaries, lagoons, deltas, river mouths, wetlands, and coral reefs) and human systems (i.e., the built environment, institutions, and human activities) (IPCC 2014, 2022a).

In general, global ocean surface temperatures have risen at an average rate of  $0.7^{\circ}\text{C} \pm 0.08^{\circ}\text{C}$  ( $1.3^{\circ}\text{F} \pm 0.1^{\circ}\text{F}$ ) per century and have risen at a higher rate from 2000 to 2016 than from 1950 to 2016 (GCRP 2018a citing Jewett and Romanou 2017; Blunden and Arndt 2017). IPCC concludes that ocean temperatures are *very likely* to increase in the future (*high confidence*), with impacts on climate, ocean circulation, chemistry, and ecosystems (IPCC 2021b). From 1971 to 2010, global oceans have absorbed more than 90 percent of all extra heat stored in earth's systems (UN 2021; Cheng et al. 2019). Ocean systems absorb approximately 25 to 30 percent of anthropogenic CO<sub>2</sub> emissions, leading to changes in ocean pH, which affects the formation of some marine species that are crucial to ocean health (GCRP 2017; UN 2021). The combination of warming and acidification across water bodies has adverse impacts on key habitats such as coral reefs and results in changes in distribution, abundance, and productivity of many marine species.

#### **Observed and Projected Climate Impacts**

Approximately 896 million people, or nearly 11 percent of the global population, were estimated to be living in the Low Elevation Coastal Zone by 2020, a figure projected to rise above 1 billion by 2050 (IPCC 2022a citing Oppenheimer et al. 2019). Globally, there will be an increasing number of people exposed to sea-level rise in the coming decades, due to high population growth from both migration and natural population increases in coastal cities, some of which are in flood- and cyclone-prone regions, increasing the number of individuals at risk (IPCC 2022a citing Neumann et al. 2015 and Hooijer and Vernimmen 2021). Without adaptation, hundreds of millions of people may be displaced due to episodic localized flooding associated with storm surge and coastal flooding and land loss from sea-level rise by 2100, with the majority from eastern, southeastern, and southern Asia (Jongman et al. 2012; GCRP 2018a; IPCC 2022a).

Even under the RCP2.6 low emissions scenario, the frequency, depth, and extent of high tide and more severe and damaging coastal flooding in the United States are projected to increase rapidly over the coming decades (GCRP 2018a). In the United States, 133.2 million people live in coastal zone counties (GCRP 2018a citing Kildow et al. 2016), and analysis indicates that 4.2 million Americans could be at risk under a scenario of 3 feet of sea-level rise, and 13.1 million people under 6 feet of sea-level rise, which could drive mass migration and societal disruption (Hauer 2017; Hauer et al. 2016).<sup>61</sup> New high-resolution digital elevation models improve estimates of potential future population exposure to sea-level rise. For example, assuming sea-level rise projections under RCP8.5, these new models reveal that up to 630 million people live on land that could be exposed to annual coastal flood levels in 2100 (Kulp

---

<sup>61</sup> The NOAA Sea Level Rise visualization tool shows inundation footprints associated with different sea-level rise simulations along the continental U.S. coast (NOAA, Office for Coastal Management, DigitalCoast, Sea Level Rise Viewer, <https://coast.noaa.gov/digitalcoast/tools/slr.html>). This and other tools can be used to understand and assess risks from sea-level rise.

and Strauss 2019). Such increases in sea-level rise and annual flooding present dramatic risks to coastal communities. Those at risk include a substantial number of individuals in a high social vulnerability category, with less economic or social mobility and who are less likely to be insured (GCRP 2018a).

Coastal inundation and flooding are the product of both long-term sea-level rise and dynamic short-term processes such as storm surge, erosion, and ocean tides (GCRP 2018a; Barnard et al. 2019). Climate change is expected to exacerbate all of these coastal processes, potentially altering coastal life and disrupting coast-dependent economic drivers and activities and services, some of which—such as transportation and energy infrastructure, and water resources—are particularly sensitive to these changes (GCRP 2018a; IPCC 2022a). Increased sea surface temperature and ocean heat content are projected to facilitate additional tropical storm activity and increase the probability of high rainfall tropical cyclones (Trenberth et al. 2018; Emanuel 2017). In turn, extreme storms can erode or remove sand dunes and other land elevations, exposing them to inundation and further change (GCRP 2018a). Rising water temperatures and other climate-driven changes (e.g., salinity, acidification, altered river flows) will affect the survival, reproduction, and health of coastal plants and animals (GCRP 2018a; UN 2021). Shifts in the distribution of species and ranges, changes in species interactions, and reduced biodiversity cause fundamental changes in ecosystems and can adversely affect economic activities such as fishing (GCRP 2018a). For instance, major marine heatwave events along the Northeast Coast of the United States in 2012 and the entire West Coast in 2014 through 2016 caused ocean temperatures to increase more than 2°C (3.6°F) above the normal range, a level similar to average conditions expected later this century under future climate scenarios (GCRP 2017). These events caused changes in the coastal ecosystems, including the appearance of warm-water species, increased mortality of marine mammals, and an unprecedented harmful algal bloom, all of which contributed to economic stress for the fisheries in these regions. While temperature is seen as the major driver of fisheries change globally, other climate-induced drivers like acidification, deoxygenation, and sea ice loss will also play significant roles in future changes to global and local fisheries (*high confidence*) (IPCC 2022a citing Cheung et al. 2019, Olsen et al. 2018, and Sampaio et al. 2021).

Species with narrow physiological tolerance to change, low genetic diversity, specific resource requirements, or weak competitive abilities will be particularly vulnerable to climate change (GCRP 2018a). For example, during the end-Permian mass extinction, a change in ocean pH of approximately 0.3, which is consistent with current projections for pH changes over the next 100 years, resulted in a loss of approximately 90 percent of known species (NRC 2013a). Under the RCP8.5 scenario, the Atlantic, Pacific, and Indian Oceans are projected to see a 15 to 30 percent decrease in total marine animal biomass by 2100. Meanwhile, polar oceans are projected to see a 20 to 80 percent decrease (Bryndum-Buchholz et al. 2018). Overall, projected shifts in fish and species distribution and decreases in their population due to climate change pose risks to income, food security, and livelihoods of marine-based communities (IPCC 2019a, 2022a).

Warming is leading to an increase in coral bleaching around the globe, with mass bleaching events and outbreaks of coral diseases affecting vulnerable reef ecosystems (GCRP 2018a). There are already 25 coral species listed under the Endangered Species Act (NOAA 2023d). Coral reefs are projected to face very high risks at 1.5°C (2.7°F) warming of global sea surface (*very high confidence*), with all coral reefs projected to degrade from their current state, even if global warming remains below 2°C (3.6°F) (IPCC 2022a citing IPCC 2019a). Updated numerical predictions show that 70 to 90 percent of coral reefs are projected to decline at a warming level of 1.5°C (2.7°F), with larger losses (more than 99 percent) at 2°C (3.6°F) (IPCC 2021a, 2022a). The potential for coastal ecosystems to pass a tipping point threshold is of particular concern because these changes can be irreversible (GCRP 2018a).

Several studies have analyzed the impact of climate change on historical and future coral bleaching. Mass coral bleaching events and disease outbreaks have increased due to more frequent and severe heat stress associated with ocean warming (*very high confidence, virtually certain*) (IPCC 2022a). For example, the Great Barrier Reef experienced mass bleaching three times between 2016 and 2020 (IPCC 2022a citing Pratchett et al. 2021). According to an analysis of bleaching records at 100 globally distributed reef locations from 1980 to 2016, the time between recurrent severe coral bleaching events has decreased steadily to 6 years during this period, and coral bleaching is occurring more frequently in all El-Niño-Southern Oscillation (ENSO) phases. These trends prevent the full recovery of mature coral assemblages between bleaching events (Hughes et al. 2018). Based on the high emissions scenario (RCP8.5), by 2055, 90 percent of reef locations are projected to experience annual severe bleaching events, and by 2034, all reef locations are projected to experience 5 percent declines in calcification. In general, the projected year of onset for annual severe bleaching events varies based on latitude, with reefs at lower latitudes expected to experience these events earlier than those at higher latitudes (van Hooijdonk et al. 2014; Sully et al. 2019).

NOAA concluded that there is *very high confidence* that global average sea level has risen by 0.16 to 0.21 meters since 1900, with a 0.07-meter rise occurring since 1993 (Sweet et al. 2017b). NOAA also estimates that global mean sea level will rise by 0.12 to 0.15 meter (0.39 to 0.49 foot) by 2030, 0.15 to 0.43 meter (0.49 to 1.4 feet) by 2050, 0.3 to 2.0 meters (0.98 to 6.56 feet) by 2100, and 0.4 to 3.7 meters (1.31 to 12.14 feet) by 2150, relative to 2000 (Sweet et al. 2022). GCRP concluded it is *extremely likely* that temperature increases account for 59 percent of the rise in global sea level during the 20th century (GCRP 2017 citing Kopp et al. 2016). The change in sea level is attributed to thermal expansion of ocean water, thawing of permafrost, and mass loss from mountain glaciers, ice caps, and ice sheets. Sea-level rise was found to be non-uniform around the world, which might result from variations in thermal expansion; exchanges of water, ocean, and atmospheric circulation; and geologic processes (IPCC 2022a; UN 2021). Higher sea levels cause greater coastal erosion; changes in sediment transport and tidal flows; landward migration of barrier shorelines; fragmentation of islands; and saltwater intrusion into aquifers, croplands, and estuaries (GCRP 2018a). Higher sea levels also result in the loss of coastal wetland environments; it was estimated that the United States lost an average of about 80,160 acres of U.S. coastal wetland environments per year between 2004 and 2009 (GCRP 2018a citing Dahl and Stedman 2013). At this rate, the United States would lose an additional 16 percent of coastal wetlands by 2100. Sea-level rise will expand floodplain areas and place more individuals in high-hazard zones; coastal communities could face increased flooding and erosion. Coastal systems and low-lying areas are expected to experience more submergence, flooding, and erosion of beaches, sand dunes, and cliffs (IPCC 2022a).

Oceans have absorbed approximately one quarter of all human-caused CO<sub>2</sub> since the preindustrial era, decreasing ocean surface pH by about 0.11 unit<sup>62</sup> (approximately 0.017 to 0.027 pH unit per decade since the 1980s), resulting in the lowest surface pH levels (i.e., highest ocean acidity) in the last 26,000 years (IPCC 2021a). The most recent projections show surface pH may decline by approximately  $-0.16 \pm 0.002$  under SSP1-2.6 and  $-0.44 \pm 0.005$  under SSP5-8.5 by 2080 to 2099 relative to 1870 to 1899; these new estimates of ocean acidity are slightly more acidic than previous estimates because the SSPs generally have higher atmospheric CO<sub>2</sub> concentrations (IPCC 2021a). IPCC concluded there is *very high confidence* that coastal areas experience considerable temporal and spatial variability in seawater pH compared to the open ocean due to additional natural and human influences including monsoons, agricultural river runoff, and internal variability (IPCC 2021a). IPCC concluded there is *high confidence*

---

<sup>62</sup> The pH scale is logarithmic; therefore, each whole unit decrease in pH is equivalent to a 10-fold increase in acidity.

that coastal acidification will continue into the 21st century but with large spatiotemporal variability as drivers of local acidity changes are influenced by biological processes, natural and anthropogenic eutrophication, sea ice melt, coastal upwelling, and seasonal dynamics (IPCC 2021a). There is high agreement that coastal acidification, regardless of cause, negatively affects marine organisms such as reef-building corals, crabs, pteropods, and sessile fauna (IPCC 2021a). Increased CO<sub>2</sub> uptake in the oceans makes it more difficult for organisms to form and maintain calcium carbonate shells and skeletal structures; increases erosion and bleaching of coral reefs and their biodiversity; and reduces growth and survival of shellfish stocks globally (GCRP 2018a). For instance, GCRP notes that under the high emissions scenario (RCP8.5), by 2100, nearly all coral reefs are projected to be surrounded by acidified seawater that would challenge coral growth (GCRP 2018a citing Ricke et al. 2013). Further, GCRP notes that under the RCP8.5 emissions scenario, by 2050, 86 percent of ecosystems will experience combinations of temperature and pH that have never before been experienced by modern species (GCRP 2018a citing Henson et al. 2017).

Hypoxia in ocean environments is a condition under which the dissolved oxygen level in the water is low enough to be detrimental to resident aquatic species. Oxygen solubility decreases as temperatures increase, with greater sensitivity at lower temperatures. As a result, warming sea surface temperatures will decrease oxygen concentrations in the ocean, especially at high latitudes where predicted rates of warming are higher. In addition, warmer sea surface temperatures enhance stratification, which prevents oxygen-rich surface water from mixing with deeper water where hypoxia typically occurs. Stratification can also be a result of sea-level rise, which increases the overall volume of shallow coastal water that is susceptible to hypoxia (Altieri and Gedan 2015). There has *very likely* been a net loss of oxygen, in the range of 0.3 to 2.0 percent over all ocean depths since the 1960s, with oxygen levels in the upper 1,000 meters (3,280 feet) of the ocean decreasing by 0.5 to 3.3 percent during 1970–2010 (*medium confidence*), with large multidecadal variations throughout the water column and across ocean basins (*high confidence*) (IPCC 2021a). Due to warming waters, stratification, and changes in precipitation, oxygen-minimum zones are expanding in the North Atlantic, the North Pacific California Current, and tropical oceans (IPCC 2022a). Models project that oxygen levels in the oceans will continue to decline through 2100 by 2.4 to 3.5 percent under the RCP4.5 and RCP8.5 emissions scenarios, respectively, with greater losses regionally and in deep sea areas (Jewett and Romanou 2017 citing Bopp et al. 2013). Decreased oxygen concentrations and hypoxia affect the physiology, behavior, and ecology of marine organisms. For instance, hypoxia has the potential to affect the visual behavior of organisms as visual tissues have high oxygen demands (McCormick and Levin 2017). Hypoxia may also cause deterioration in the reproductive systems of both male and female fish, leading to a significant decrease in hatching success (Lai et al. 2019). The ability of marine organisms to survive in hypoxic conditions is further strained by warming ocean temperatures. Marine benthic organisms (i.e., organisms that live on or near the ocean floor) have been shown to have significantly shortened survival times when subjected to warmer hypoxic conditions (Vaquer-Sunyer and Duarte 2011).

Ocean salinity levels can be affected by freshwater additions, ocean evaporation, and the freezing or thawing of ice caps and glaciers. Marine organisms are adapted to specific levels of ocean salinity and often become stressed by changing salinity levels. Additionally, changing ocean salinity levels affect the density of water, which in turn affects factors such as the availability of local drinking water and, potentially, global ocean circulation patterns. Although the globally averaged salinity change is small, changes in regional basins have been significant. On a regional scale, projected trends over the 21st century indicate that fresh ocean regions will continue to get fresher and salty ocean regions will continue to get saltier (*medium confidence*) (IPCC 2021a). Evaporation-dominated subtropical regions are exhibiting definite salinity increases, while regions dominated by precipitation are undergoing

increasing freshening in response to intensification of the hydrological cycle (IPCC 2021a; UN 2021). These effects are amplified in regions that are experiencing increasing precipitation or evaporation. Findings through surface water analyses of the Atlantic Ocean show increased salinity, while the Pacific Ocean demonstrates decreased salinity, and the Indian Ocean has observed minimal changes (Durack and Wijffels 2010).

Net primary production refers to the net flux of carbon from the atmosphere into organic matter over a given period.<sup>63</sup> Ocean systems provide approximately half of global net primary production. Net primary production is influenced by physical and chemical gradients at the water surface, light, and nutrient availability. A changing climate alters the mixed layer depth, cloudiness, and sea-ice extent, thus altering net primary production. Global mean net primary productivity of oceans is projected to decline by 2080 to 2099 relative to 2006 to 2015 under all scenarios with considerable regional variations, ranging from large declines in the North Atlantic and western equatorial Pacific to consistent productivity increases in the high latitudes (IPCC 2022a citing Kwiatkowski et al. 2020). Impacts on primary productivity vary significantly across regions. While primary productivity in the tropics and temperate zones is projected to decrease, primary productivity in high-latitude regions, particularly the Arctic, showed positive trends from 2003 to 2021 in all nine regions, with statistically significant trends occurring in two regions—the Eurasian Arctic and the Barents Sea (NOAA 2022).

### **Adaptation**

The primary adaptation options for sea-level rise include *protection*, *accommodation*, *advance*, and *retreat*—all of which are widely used around the world (IPCC 2022a citing Cooley et al. 2022, Glavovic et al. 2022, and Oppenheimer et al. 2019). *Protection* is the creation of barriers against sea intrusion, through a variety of hard engineering (e.g., sea walls and dikes), soft engineering (e.g., beach nourishment) and nature-based measures (e.g., mangrove protection). *Accommodation* is achieved by increasing the flexibility of infrastructure and adjusting the use of at-risk coastal zones, for example, through flood proofing and spatial planning (IPCC 2022a). An *advance* strategy creates new land by building seaward, which can reduce risk for the hinterland or the newly elevated land, for example, through land filling. *Retreat* allows the impacts of sea-level rise to occur unobstructed as inhabitants pull back from inundated coastlines, such as through adaptive migration, planned relocation, or involuntary displacement.

Ecosystem-based protection strategies, which include the protection and restoration of coastal ecosystems like oyster reefs, mangroves, and salt marshes are increasingly attracting attention (IPCC 2022a citing Beck et al. 2018 and Narayan et al. 2016). In addition, reducing non-climate stresses (e.g., coastal pollution, overfishing, development) may increase the climate resilience of framework organisms (i.e., tropical corals, mangroves, and seagrass) (World Bank 2013; Ellison 2014; Anthony et al. 2015; Sierra-Correa and Cantera Kintz 2015; Kroon et al. 2016; O’Leary et al. 2017; Donner 2009).

While many coastal adaptation plans call for risk identification, monitoring, research, and planning, required financial resources for implementation and capacities of communities to adapt equitably need to be increased (GCRP 2018a). Some examples of coastal adaptation include integrating natural

---

<sup>63</sup> Net primary production is estimated as the amount of carbon synthesized via photosynthesis minus the amount of carbon lost via cellular respiration.

landscape features with built infrastructure (green and gray infrastructure<sup>64</sup>) to reduce stormwater runoff and wave attack, constructing seawalls around wastewater treatment plants and pump stations, pumping effluent to higher elevations as sea levels rise, pumping fresh water into coastal aquifers to mitigate saltwater infiltration, developing flood-proof infrastructure, relocation of coastal infrastructure away from the coast, and relocation of communities away from high-hazard areas (GCRP 2018a). Some examples of ocean adaptation include reducing overfishing; establishing marine protected areas; conserving habitat to increase resilience; restoring and conserving coastal ecosystems like oyster reefs, mangroves, and coral reefs; and developing alternative livelihood options for marine food-producing sectors (GCRP 2018a).

#### **E.5.2.4 Food, Fiber, and Forest Products**

Increases in atmospheric CO<sub>2</sub>, combined with rising temperatures and altered precipitation patterns, have begun to affect both agricultural and forest systems (Walthall et al. 2013; GCRP 2015, 2018a; IPCC 2022a; U.S. Department of Agriculture [USDA] 2015, 2020; U.S. Forest Service [USFS] 2016; Food and Agriculture Organization of the United Nations [FAO] 2015, 2022). These impacts are expected to become more severe and to affect food security (FAO 2015; GCRP 2015).

#### **Observed and Projected Climate Impacts**

Climate change has slowed the growth of agricultural production over the past 50 years and will put pressure on food production and access, particularly undermining food security in vulnerable regions. It is projected that current global crop and livestock areas will increasingly become climatically unsuitable—an estimated 8 percent under SSP1-2.6 and 30 percent under SSP5-8.5 by 2100. Though a few regions may experience some beneficial effects in the near future, overall impacts on terrestrial and aquatic food systems will become increasingly negative (IPCC 2022a). Currently, yields for some crops are increasing; however, climate change could be diminishing the rate of these increases. It is estimated that global crop yield reduction due to climate change is about 1 percent per decade, with median yield declines for major crops ranging from 0.7 percent for rice to 1.3 percent and 2.3 percent for wheat and maize, per decade, respectively (IPCC 2022a citing Porter et al. 2014). Generally, yields and food security are at greater risk in less-developed, low-latitude countries (FAO 2015; GCRP 2015), concentrated in Sub-Saharan Africa, South Asia and Central America (IPCC 2022a).

Increased frequency and intensity of extreme weather events is expected to negatively influence crop, livestock, and forest productivity and increase the vulnerability of agriculture and forests to climate risks (Walthall et al. 2013; GCRP 2018a; IPCC 2022a; USDA 2015, 2020; EPA 2016f; USFS 2016; Vogel et al. 2019b). Increases in frequency and intensity of droughts, floods, heatwaves, and continued sea-level rise will increase risk to food security (*high confidence*) from moderate to high between 1.5°C (2.7°F) and 2°C (3.6°F) global warming levels, assuming no to low levels of adaptation (IPCC 2022a). Specific climate impacts on agriculture will vary based on the species, location, timing, and current productivity of agricultural systems (including crops, livestock, and fish) at local, national, and global scales (IPCC 2022a; USDA 2015).

Bench- and field-scale experiments have found that over a certain range of concentrations, greater CO<sub>2</sub> levels have a fertilizing impact on plant growth (e.g., Long et al. 2006; Schimel et al. 2000) with

---

<sup>64</sup> Green infrastructure refers to sustainable pollution-reducing practices that also provide other ecosystem services (e.g., permeable pavements, green roofs). Gray infrastructure refers to traditional practices for stormwater management and wastewater treatment, such as pipes and sewers.

considerable variability among regions and species (McGrath and Lobell 2013). However, climate change is projected to cause multiple abiotic (nonliving) stressors (e.g., temperature, moisture, extreme weather events), and biotic (living) stressors (e.g., disease, pathogens, weeds, insects) on crop production (Thornton et al. 2014; IPCC 2022a; GCRP 2017, 2018a). Climate change impacts on agriculture may also affect socioeconomic conditions, such as the amount of crop insurance paid to cover losses from extreme climate conditions (Walsh et al. 2020).

Additionally, climate change is projected to affect a wide range of ecosystem processes, including maintenance of soil quality and regulation of water quality and quantity (GCRP 2018a; USDA 2015). Changes in these and other ecosystem services will exacerbate stresses on crops, livestock, and forests (Walthall et al. 2013; GCRP 2018a). Major staple crops (wheat, rice, maize, and soybean) could suffer reduced yields between 3 and 7.4 percent for each degree-Celsius increase in global mean temperature (Zhao et al. 2017).

Livestock are vulnerable because climate change affects the nutritional quality of pastures and grazing lands; affects the production, availability, and price of feed-grains; stresses animals; hurts overall animal well-being (i.e., animal health, growth, and reproduction and distribution of animal diseases and pests); and decreases livestock productivity (e.g., meat, milk, and egg production) (IPCC 2022a citing Rojas-Downing et al. 2017, Godde et al. 2021, Stanimirova et al. 2019, Sloat et al. 2018, Bett et al. 2017, and Naqvi et al. 2015; GCRP 2015; GCRP 2018a citing Key et al. 2014, Amundson et al. 2006, Dash et al. 2016, Rojas-Downing et al. 2017, Giridhar and Samireddypalle 2015, Lee et al. 2017, Paul et al. 2007, and Zhorov 2013).

Studies have concluded that climate change is affecting aquatic ecosystems, including marine and freshwater fisheries (IPCC 2022a; Groffman et al. 2014). Climate change impacts on marine fisheries have primarily been linked to increasing temperatures (including both mean and extreme temperatures) but are also affected by increasing CO<sub>2</sub> concentrations and ocean acidification (IPCC 2022a; GCRP 2018a). Fisheries are affected by increases in ocean temperatures, resulting in many marine fish species migrating to deeper or colder water, additional stress to already strained coral reefs, and an expansion in warm freshwater habitats and a shrinkage of cool and cold freshwater habitats (IPCC 2022a; NOAA 2015a). FAO estimates that by 2050, the average total marine maximum catch potential in the world's Exclusive Economic Zones could decline by 7 to 12 percent (relative to 2000) under a higher emissions scenario (RCP8.5); by 2100, this decrease could be as much as 16 to 25 percent (Bell and Bahri 2018 citing FAO 2018). However, these decreases would not be consistent around the globe. Another study found that fisheries productivity could experience a decline in maximum catch potential of 10 to 47 percent compared to the 1950 to 1969 level under RCP8.5 in the contiguous United States and experience an increase in potential of 10 percent in the Gulf of Alaska and 46 percent in the Bering Sea (GCRP 2018a citing Cheung et al. 2016).

Climate change threatens forests by increasing tree mortality and forest ecosystem vulnerability due to fire, insect infestations, drought, disease outbreaks, increasing temperatures, and extreme weather events (Joyce et al. 2014; IPCC 2022a; USFS 2016; GCRP 2018a; Aleixo et al. 2019; Williams et al. 2019). Currently, tree mortality is increasing in many parts of the globe due to warmer and drier than average conditions (IPCC 2022a). It is projected that tree mortality will increase with climate change as forests become more exposed to extreme events like heatwaves, droughts, and storm, and due to increased incidences of wildfires (IPCC 2022a). GCRP estimates that water-limited forests will be further constrained by a warmer climate, while energy-limited forests may experience an increase in growth due to climate change (GCRP 2018a).

Other climate-change-induced direct and indirect effects, such as 1) changes in the distribution and abundance of insects and pathogens, 2) fire, 3) changes in precipitation patterns, 4) invasive species, and 5) extreme weather events (e.g., high winds, ice storms, hurricanes, landslides), are also affecting forests (GCRP 2017; Thornton et al. 2014; IPCC 2022a). A dramatic increase in the area burned by wildfire and risk of wildfire is projected in the contiguous United States through 2100, especially in the West (EPA 2015d; Halofsky et al. 2017; Tett et al. 2018). In the past 4 decades, burned area from wildfires has roughly quadrupled in the United States due to a variety of factors, one of which is a recent increase in fuel aridity, which is expected to continue to increase as the climate changes (Burke et al. 2021 citing National Interagency Fire Center 2020). Moreover, in recent years, there has been record-breaking wildfire activity in areas not typically prone to wildfires, such as the Arctic and the Amazon (United Nations Environment Programme [UNEP] and GRID-Arendal 2022). Tree species are predicted to shift their geographic distributions to track future climate change (Zhu et al. 2014; USFS 2016).

Forests serve as a net carbon sink globally but are projected to become less effective at capturing accumulated CO<sub>2</sub> as GHG emissions increase (IPCC 2021b). Carbon storage is expected to generally decrease in the future due to increased temperatures, more frequent droughts, increased disturbances such as pest outbreaks and wildfires, and current trends in land use and forest management, making it difficult to predict whether forests will continue to serve as a net carbon sink in the future (Joyce et al. 2014; GCRP 2018a; IPCC 2022a). For example, impacts of climate change coupled with deforestation and agricultural expansion have caused the Amazon rainforest to become an overall net carbon emitter between 2010 to 2019 (IPCC 2022a citing Qin et al. 2021 and Hubau et al. 2020). In addition, historic land uses have a legacy effect on patterns of carbon uptake in forests, further complicating the calculation of future CO<sub>2</sub> sequestration patterns (Thom et al. 2018).

Climate change impacts on food security and food systems are predicted to be widespread, complex, geographically and temporally variable, and greatly influenced by socioeconomic conditions (IPCC 2022a). For example, smallholder farmers—a group that suffers from chronic food insecurity—are especially vulnerable to the risks of pests, diseases, and extreme weather events that are made worse by climate change (Mbow et al. 2019). An additional challenge for food security will be future population growth, with global population projected to reach 9.8 billion by 2050 (GCRP 2018a citing Hallström et al. 2015, Harwatt et al. 2017, UN Department of Economic and Social Affairs 2017). Climate change, through direct and indirect pathways, adversely affects all four pillars of food security—availability, access, utilization, and stability—all of which are closely tied to underlying socioeconomic factors like poverty and inequality (IPCC 2022a). Projected rising temperatures, changing weather patterns, and increases in the frequency of extreme weather events will affect food security by potentially altering agricultural yields, post-harvest processing, food and crop storage, transportation, retailing, and food prices (GCRP 2018a; IPCC 2022). Many of these impacts are expected to be negative, including decreasing production yields; harming pollinators; increasing costs and spoiling during processing, packaging, and storage; inhibiting water, rail, and road transportation; and increasing food safety risks (GCRP 2015; Giannini et al. 2017). The negative consequences of climate change—decreased crop yields, nutrition, and food security—are projected to be more severe under 2°C (3.6°F) of warming than under 1.5°C (2.7°F) of warming (*high confidence*) (IPCC 2018).

Currently, the vast majority of undernourished people live in developing countries (IPCC 2022a). Both due to the nature of the direct impacts and the means to implement adaptation strategies, climate change poses the greatest food security risks to poor and tropical region populations, and the least risk to wealthy, temperate, and high-latitude region populations (GCRP 2015; FAO 2015). As most countries import at least some of their domestic food consumed, climate change has the potential to affect not

just food production but also the amount of food that countries import and export. Import demand is expected to increase for developing nations lacking advanced technologies and practices and producing low agricultural yields (GCRP 2015).

### ***Adaptation***

Over the past 150 years, the agricultural and forestry sectors have demonstrated an impressive capacity to adapt to a diversity of growing conditions amid dynamic social and economic changes (Walthall et al. 2013; Joyce et al. 2014; FAO 2015; GCRP 2015). Recent changes in climate, however, threaten to outpace the current adaptation rate and create challenges for the agricultural sector and associated socioeconomic systems (GCRP 2018a; IPCC 2022a). Economic literature indicates that in the short term, producers will continue current adaptation practices for weather changes and shocks (e.g., by changing timing of field operations, shifting crops grown, changing tillage/irrigation practices) (GCRP 2018a). In the long term, however, current adaptation technologies are not expected to buffer the impacts of climate change sufficiently (GCRP 2018a). In fact, significant shifts in crop choice and land-use patterns will be required in order to sustain production growth and match global demand (Mbow et al. 2019).

To minimize these impacts, a variety of resilience actions can be implemented, including management and policy, engineering, and insurance responses. Management practices associated with sustainable agriculture, such as diversifying crop rotations and crop varieties, integrating livestock with crop production systems, improving soil quality, and minimizing off-farm flows of nutrients and pesticides can increase resiliency to climate change (GCRP 2018a citing Walthall et al. 2012, Rojas-Downing et al. 2017, Yorgey et al. 2017, and Abberton et al. 2016; Li et al. 2019). Furthermore, the use of heat- and stress-tolerant and other adaptively advantageous varieties of crops can increase yield in the face of climate change (Zhang and Zhao 2017; GCRP 2018a). Enhancing genetic resources via genetic modification and improved breeding systems also has potential to enhance crop resilience (GCRP 2015 citing Jacobsen et al. 2013 and Lin 2011).

For livestock, adaptive capacity is limited by high costs and competition. Possible adaptation measures include breeding livestock to genetically adapt to local conditions, improving the design of livestock housing, and implementing management strategies that cool livestock and reduce stress (GCRP 2018a). However, cooling strategies are not always economically feasible due to high infrastructure and energy demands (GCRP 2015). Furthermore, increased shade and moisture can heighten pathogen risk (Fox et al. 2015). Irrigation strategies to improve feed quality and quantity could also be limited by competition with other water users, especially in arid climates (GCRP 2015 citing Elliott et al. 2014). To enhance resilience against increased pathogen risk, adaptation strategies include no-regrets strategies, disease surveillance and response, disease forecast capacity, animal health service delivery, eradication of priority diseases, increased diversification and integration of livestock with agriculture, breeding resilient animals, and monitoring impacts of land-use change on disease (Grace et al. 2015). Fisheries have developed a number of adaptation practices as well. For example, NOAA's Climate Science Strategy (2015b) has the objective of designing adaptive decision processes to enable fisheries to enhance fishery resilience.

Forest management responses to climate change will be influenced by the changing nature of private forestland ownership, globalization of forestry markets, emerging markets for bioenergy, and climate change policy (Walthall et al. 2013; Joyce et al. 2014). The emerging market for bioenergy—the use of plant-based material to produce energy—has the potential to aid in forest restoration (Joyce et al. 2014). At the same time, possible projected declines in a skilled forest sector workforce and timber product output (and lower prices for timber) could pose a challenge to climate change adaptation of

forests (GCRP 2018a citing USFS 2016). Flexible policies that are not encumbered with legally binding regulatory requirements can facilitate adaptive management where plants, animals, ecosystems, and people are responding to climate change (Joyce et al. 2014 citing Millar and Swanston 2012). Ultimately, maintaining a diversity of tree species could become increasingly important to maintain the adaptive capacity of forests (Duveneck et al. 2014). Carbon sequestration losses can be mitigated using sustainable land-management practices (GCRP 2015 citing Branca et al. 2013).

In terms of food security, global undernourishment dropped from 19 percent in 1990 to 11 percent in 2014 (GCRP 2015). However, global undernourishment has been increasing in recent years, from 8 percent in 2019 to 9.3 percent in 2020 and 9.8 percent in 2021 (FAO et al. 2022). This recent increase is due largely to the COVID-19 pandemic, but it is unclear what future trends will look like, particularly with other global stressors such as the war in Ukraine as well as the challenges posed by climate change (FAO et al. 2022; GCRP 2015). Developing and implementing new agricultural methods in low-yield regions, reducing waste in the food system, making food distribution systems more resilient to climate risks, protecting food quality and safety at higher temperatures, and creating policies to ensure food access for disadvantaged populations during extreme events are all adaptation strategies to mitigate the effects of climate change (GCRP 2015, 2018a; IPCC 2022a). Ultimately, adaptation will become more difficult as physiological limits of plant and animal species are exceeded more frequently and the productivity of crop and livestock systems becomes more variable (GCRP 2018a).

#### **E.5.2.5 Urban Areas**

Urban centers are now home to more than half of the global population, and this percentage continues to increase every year (IPCC 2022a). Global urban populations grew by more than 397 million people between 2015 and 2020, with more than 90 percent of this increase concentrated in less developed countries (IPCC 2022a). More recent estimates project approximately 60 percent of the global population will reside in urban areas by 2030, with more people living in unplanned and informal settlements (IPCC 2021a; IPCC 2022a citing UN Department of Social and Economic Affairs 2018). In the United States, approximately 85 percent of the population lives in metropolitan areas<sup>65</sup> (GCRP 2018a). In addition to large numbers of people, urban centers also contain a great concentration of the world's economic activity, infrastructure, and assets (IPCC 2022a; GCRP 2018a).

Wealthy nations are predominantly urbanized, and low- and middle-income nations are rapidly urbanizing. Urbanization processes generate vulnerability and exposure that interact with climate hazards, resulting in urban risk and impacts (*high confidence*) (IPCC 2022a). The rate of urbanization is outstripping the rate of investment in basic infrastructure and services, which is creating urban communities with high vulnerability to climate change, especially in unplanned and informal settlements (IPCC 2022a citing Angel et al. 2016, Banks et al. 2020, and Myers 2021). Across urban communities, there are very large differences in the extent to which economies are dependent on climate-sensitive resources, but in general, a high proportion of people most at risk of extreme weather events are located in urban areas (IPCC 2022a). The most economically and socially marginalized people in urban areas are the most affected by climate impacts (*high confidence*) (IPCC 2022a).

---

<sup>65</sup> Metropolitan areas include urbanized areas of 50,000 or more population, plus adjacent territory that has a high degree of social and economic integration (Office of Management and Budget 2010).

### **Observed and Projected Climate Impacts**

The risks of climate change to urban communities and their populations' health, livelihood, and belongings are increasing. Risks include rising sea levels, storm surges, extreme temperatures, extreme precipitation events leading to inland and coastal flooding and landslides, drought leading to increased aridity and water scarcity, and various combinations of stressors exacerbating air pollution (IPCC 2022a; GCRP 2018a). It cannot be assumed that climate change impacts will be the same or even similar in different cities (Silver et al. 2013). In addition, certain population groups may be more directly affected by climate change than other groups. For example, the very young and elderly are both more sensitive to heat stress, some communities of color and tribal and Indigenous communities are disproportionately exposed to health risks related to climate hazards, those with preexisting health issues could be more sensitive to a range of stressors, and low-income groups and women could be more sensitive due to a lack of resources and discrimination in access to support services (Ebi et al. 2018; IPCC 2022a; Cutter et al. 2014; GCRP 2018a). In turn, some populations most vulnerable to climate-related health hazards also experience greater challenges in accessing information, resources, and tools for building resilience to climate change (Ebi et al. 2018).

Cities that are projected to experience rising temperatures are apt to experience temperatures even higher than projected due to the urban heat island effect (whereby the volume of paved land in urban areas absorbs and holds heat along with other causes) (GCRP 2018a citing Hibbard et al. 2017; IPCC 2022a citing Oke et al. 2017, Susca and Pomponi 2020, and Doblas-Reyes et al. 2021). Heatwaves are also projected to worsen, and half of the future urban population will be affected by extreme heat events (IPCC 2022a). This could lead to increased health impacts, air pollution, and energy demand, disproportionately affecting low-income, young, historically underserved, and elderly populations (IPCC 2022a citing Chambers 2020, Sabrin et al. 2020, and Quintana-Talvac et al. 2021). Urbanization, through increased impermeable surfaces and microclimatic changes, can also increase flooding. Climatic trends, such as increased frequency of extreme precipitation and sea-level rise, will stress existing flood infrastructure (GCRP 2017; National Academies of Sciences, Engineering, and Medicine 2019).

Drought and reduced snowpack will have many effects in urban areas, including water shortages, electricity shortages (from decreased hydropower operation), water-related diseases (which could be transmitted through contaminated water), and food insecurity. Changes in precipitation due to climate change could exacerbate existing water demand conflicts, both within cities and across regions (IPCC 2022a citing Garrick et al. 2019, Moser and Hart 2015, and Liu et al. 2018). Sea-level rise and increases in tropical cyclone storm surge can also increase the probability of coastal city flooding (*high confidence*) (IPCC 2022a). Sea-level rise will also result in increased salinization of groundwater, estuaries, wetlands, and soils, which will further constrain water availability and quality (IPCC 2022a). Increased eutrophication from warming water temperatures will incur costs related to upgrading municipal drinking water treatment facilities and purchase of bottled water. Additionally, sea-level rise poses a risk to water treatment facilities (Baron et al. 2013).

In developed and developing countries, stormwater systems will be increasingly overwhelmed by extreme short-duration precipitation events if they are not upgraded (IPCC 2022a citing Flood and Cahoon 2011, Trtanj et al. 2016, Hummel et al. 2018, Kirshen et al. 2018, Nazarnia et al. 2020, Reznik et al. 2020, and McKenzie et al. 2021). If storm drains for transportation assets are blocked, then localized flooding can cause delays (GCRP 2014).

Climate change will have direct impacts on both the production and the demand side of the energy system. For example, individual or combinations of hazards may increase risk of direct physical damage

to generation as well as transmission and distribution systems, reduce the efficiency of water cooling for large thermoelectric electricity generating facilities, reduce water availability for hydroelectric and wind power potential, and change demands for heating and cooling in developed countries (GCRP 2018a; IPCC 2022a; National Academies of Sciences, Engineering, and Medicine 2017a). Many power supply facilities such as power plants, refineries, pipelines, transmission lines, substations, and distribution networks are located in coastal environments and are thus subject to direct physical damage and permanent and temporary flooding from sea-level rise, higher storm surge and tidal action, increased coastal erosion, and increasingly frequent and intense storms and hurricanes (GCRP 2018a). The facilities may also be negatively affected by the vulnerability of transportation systems that provide feedstocks such as coal (DOE 2015 citing DOE 2013; Ingram et al. 2013).

Climate change impacts that decrease the reliability of, or cause disruptions to, the energy supply network could have far-reaching consequences on businesses, infrastructure, health care, emergency services, residents, water treatment systems, traffic management, and rail shipping (GCRP 2018a; IPCC 2022a citing Groundstroem and Juhola 2019 and Cronin et al. 2018). Oil and gas availability for transportation in the United States would also be affected by increased energy demand in global markets as well as by climate change events. For example, DOE (2015) concluded that 9 percent of U.S. refining capacity could be exposed to sea-level rise and storm surge in 2050 (assuming 23 inches of sea-level rise and a Category 3 storm), and strategic petroleum reserves may be exposed to flooding during lower-intensity storms.

The daily and seasonal operation of most transportation systems is already sensitive to fluctuations in precipitation, temperature, winds, visibility, and for coastal cities, rising sea levels (GCRP 2018a citing Niemeier et al. 2013, Schwartz et al. 2014, and Chinowsky et al. 2017; IPCC 2022a). With climate change, the reliability and capacity of the transportation network could be diminished from increased frequency of flooding and heat events and increased intensity of tropical storms (GCRP 2018a; DOT 2019a). Information and communication technology (ICT) infrastructure is already vulnerable to climate risks. Impacts on ICT components include flooding of electrical support systems, wind, ice and snow damage to overhead cables, corrosion due to flooding and sea-level rise, heatwave-induced ground shrinkage and damage to underground ICT assets, and unstable foundations due to warming-induced permafrost melt (IPCC 2022a citing Fu et al. 2016 and Shiklomanov et al. 2017).

Housing in urban areas is heavily affected by extreme weather events such as cyclones, floods, and fires, causing both physical damage and loss of property value (IPCC 2018a). Housing that is constructed out of informal building materials (usually occupied by low-income residents) and without strict building codes is particularly vulnerable to extreme events (IPCC 2022a). Loss of housing due to extreme events and shifts in climate patterns is linked to displacement, loss of home-based businesses, and health and security issues (IPCC 2022a). Some of the climate impacts described here (e.g., property damage associated with greater flood risk) are sometimes described as costs of carbon in analyses of the social cost of carbon (National Academies of Sciences, Engineering, and Medicine 2017b).

Climate change will also affect urban public services such as health care and social care services, education, police, and emergency services (IPCC 2022a citing Corvalan et al. 2020 and Hierink et al. 2020). The links between city sectors can mean that climate stressors have cascading impacts across sectors; these impacts increase risk to urban dwellers' health and well-being and make urban areas more vulnerable to disruptions (GCRP 2018a citing Torres and Maletjane 2015). Water shortages can lead to reliance on poorer quality water sources and can increase the likelihood of contracting waterborne illnesses. Changes in temperature extremes will also affect health through heat stress and

changes in air quality (IPCC 2022a); however, impacts of climate change on air quality in particular locations are highly uncertain (IPCC 2022a citing Weaver et al. 2009 and Baklanov et al. 2016).

### ***Adaptation***

Adapting urban centers will require substantial coordination between the private sector, multiple levels of government, and civil society (GCRP 2018a; GCRP 2018a citing Department of the Interior Strategic Sciences Group 2013, C40 Cities Climate Leadership Group and Arup 2015, and Arup et al. 2013), but early action by urban governments is key to successful adaptation because adaptation measures need to be integrated into local investments, policies, and regulatory frameworks (IPCC 2022a). Existing risk reduction plans, such as public health and natural hazard mitigation plans, provide strong foundations for the development of more comprehensive and forward-thinking documents that address increasing exposure and vulnerability (IPCC 2022a). Embedding adaptation into existing plans and decision-making processes (e.g., multi-hazard mitigation plans, long-term water plans, permitting review processes) helps to institutionalize adaptation (Aylett 2015; GCRP 2018a citing Bierbaum et al. 2013, Hughes 2015, and Rosenzweig et al. 2015). Taking a long-term view toward planning is important so that future climate impacts do not undermine plans put in place now (GCRP 2018a). Although many more cities have adopted adaptation plans since IPCC AR5, there remains a large gap between planning and implementation, mainly due to lack of governance and management capacity, limited financial mechanisms, and competing priorities (IPCC 2022a). Financing adaptation strategies could be one of the largest hurdles to overcome; however, urban adaptation can enhance the economic competitiveness of an area by reducing risks to businesses, households, and communities (IPCC 2022a). Additionally, there are emerging synergistic options for urban adaptation measures that also deliver GHG emissions reduction co-benefits (IPCC 2022a).

#### ***E.5.2.6 Rural Areas***

This section discusses existing vulnerabilities in rural areas, associated climate change impacts, and potential adaptation strategies. It is difficult to consistently define rural areas because human settlements exist along a continuum from urban to rural with many varied land-use forms in between; moreover, there are varying development patterns between developed and developing countries (IPCC 2022a). IPCC describes rural settlements as those with low population density and a high proportion of people engaged in the agricultural sector for their livelihoods (IPCC 2022a).

The Organization for Economic Co-operation and Development (OECD) estimates that 24 percent of the global population lives in rural areas (IPCC 2022a citing OECD and European Commission 2020). The U.S. Census Bureau classifies more than 97 percent of the land area in the United States as rural but only 20 percent of the population calls these areas home (U.S. Census Bureau 2020). Rural areas tend to have a higher percentage of people living in poverty than urban areas, in addition to having lower education and lower wages for the same level of education than people in urban areas (GCRP 2018a).

### ***Observed and Projected Climate Impacts***

Rural livelihoods and incomes are mostly based on farming, livestock rearing, and natural resources that are inherently sensitive to climate variability and change (IPCC 2022a citing Viswanathan and Kumar 2015 and Bohra-Mishra et al. 2017; GCRP 2018a). Due to their dependence on natural resources and reliance on weather-dependent activities, rural communities are subject to unique vulnerabilities to climate change (GCRP 2018a). In addition, rural communities often lack economic diversity and have limited access to the internet and limited critical infrastructure, making it more difficult for communities

to adjust to climate disturbances (GCRP 2018a; IPCC 2022a). Due to the lack of economic diversity, climate change will place disproportionate stress on the stability of rural communities, also referred to as a *climate gap* (GCRP 2018a). Rural vulnerabilities also have the potential to affect urban areas significantly; for example, drought experienced in rural areas can decrease food production and contribute to food insecurity in urban areas (IPCC 2022a).

An increase in extreme climate-induced events will have a negative impact on rural areas and their agricultural production. Tropical storms, extreme flooding, and droughts have led to a rise in food rates and created severe food crises (IPCC 2022a). Extreme heat has also posed challenges to human and livestock health from increased frequency of extreme temperatures (IPCC 2022a; GCRP 2018a). Heat stress has caused livestock production to decrease in productivity, caused livestock to experience increased mortality rates, and resulted in large economic losses for producers (IPCC 2022a; GCRP 2018a).

Rural areas frequently depend on groundwater extraction and irrigation for local agriculture (IPCC 2022a). In the United States, groundwater is responsible for more than 40 percent of water used in agriculture (GCRP 2018a). In some areas, irrigation has exceeded the natural aquifer recharge rates, shrinking water availability (GCRP 2018a). In the future, increased evaporation caused by warming temperatures, in addition to drought conditions, will deplete surface water and groundwater resources and increase stress on irrigation systems (GCRP 2018a). In the long term, it is projected that irrigated acreage will decrease due to the decline of water availability and the decreasing profitability of irrigated crops (GCRP 2018a).

Soil erosion is also a threat to rural communities and agricultural productivity (GCRP 2018a). Extreme precipitation events are expected to increase in frequency due to climate change within many regions of the United States (GCRP 2018a). This will consequently increase the potential for soil to be eroded and reduce agricultural productivity (GCRP 2018a). In addition, major flooding events can lead to soil and water degradation in rural communities and decrease economic activity (GCRP 2018a). For more information on climate impacts on agriculture, see Section E.5.2.4, *Food, Fiber, and Forest Products*. Nonfood crops and high-value food crops such as cotton, rice, corn, wheat, wine grapes, beverage crops (coffee, tea, and cocoa), and other cash crops contribute to an important source of income to rural locations. Negative impacts of climate change on a variety of crop types, including cash crops, have already been documented (GCRP 2018a; IPCC 2022a).

Impacts of climate change on rural infrastructure are similar to those in urban areas (see Section E.5.2.5, *Urban Areas*), but frequently there is less redundancy in rural systems, so assets are more vulnerable to hydroclimatic events (GCRP 2018a). Rural communities are becoming more connected to urban ones, but human migration from rural to urban areas is not necessarily any greater due to climate change than under regular conditions (IPCC 2022a). Migration will increase following extreme events that lead to the desertion of local communities (e.g., extreme storms), but migration from slow environmental degradation (e.g., sea-level rise) is anticipated to be minimal. Generally, more migration is linked to additional stressors such as political instability and socioeconomic factors (IPCC 2022a). It is possible that factors such as increased temperatures and natural disasters will spur migration, but the underlying force may be the adverse consequences of climate change on agriculture (Bohra-Mishra et al. 2017).

Rural communities that are economically reliant or centered around rural landscapes for tourism are also vulnerable to the impacts of climate change (IPCC 2022a). Declining snow cover, increase in wildfire smoke, and animal migration shifts are just some climate-related impacts that are expected to decrease tourism in rural areas (IPCC 2022a). Coastal tourism infrastructure is vulnerable to sea-level rise, storm

surge, and coastal erosion (IPCC 2022a). Additionally, an increase in algal blooms and changes in wind and precipitation patterns can threaten coastal tourism in North America (IPCC 2022a). Nature-based tourism in tropical forests may be affected by the declining rate of biodiversity and consequently experience a decline in nature trekking (IPCC 2022a). Glacier melting may also reduce nature trekking and other nature-based tourism activities (IPCC 2022a). Winter sport tourism and recreation are also negatively affected by changes in seasonality and shifts in precipitation as more precipitation is falling as rain rather than snow (IPCC 2022a).

### **Adaptation**

Some feasible and effective adaptation options for people living in rural areas include the provision of basic services, livelihood diversification, and strengthening of food systems (*high confidence*) (IPCC 2022a). Providing critical infrastructure, for example, through renewable energy projects, can provide many co-benefits (IPCC 2022a). Biodiversity management strategies can also provide multiple social co-benefits to rural communities, including improved community health and opportunities for recreational activities and ecotourism. Climate-smart agricultural initiatives, such as cover crops, specialized irrigation, and nutrient management, can also help rural communities prepare for climate variability and change (GCRP 2018a), while strengthening local and regional food systems and building resilience and self-reliance (IPCC 2022a).

While rural lands and rural communities have the potential to make significant contributions to climate change mitigation and adaptation, these opportunities are limited by socioeconomic and demographic factors (GCRP 2018a). Adaptations in rural communities face challenges posed by the lack of economic diversity, relatively limited infrastructure and resources, and limited political influence (GCRP 2018a citing U.S. House of Representatives 2017, Kuttner 2016, and Williamson et al. 2012). Adaptation efforts should focus on serving vulnerable populations and ensuring that an inclusive, equitable, and evidence-based decision process is followed (IPCC 2022a).

#### **E.5.2.7 Human Health**

This section provides an overview of the recent findings regarding observed and projected impacts of climate change on the human health sector in the United States and globally. This section describes the climate impacts related to extreme events, heat and cold events, air quality, aeroallergens, water- and food-borne diseases, vector-borne diseases, cancer, and indirect impacts on health. Effects of climate change on human health range from direct impacts from extreme temperatures and extreme weather events to changes in prevalence of diseases, and indirect impacts from changes to agricultural productivity, nutrition, conflict, and mental health (IPCC 2022a). However, vulnerability to health risks varies across subpopulations and geographic areas. Both globally and within the United States,<sup>66</sup> populations that are particularly vulnerable include those in vulnerable life stages such as pregnant and nursing women, the elderly, and children in all age groups; those with comorbidities and disabilities; those living alone; those experiencing homelessness, mental illness, or substance abuse; those living in inadequate housing; Indigenous and minority populations; outdoor workers; low-income residents lacking social support networks; those with less access to health care, including the uninsured and underinsured; and those with limited financial resources to rebound from disasters (Watts et al. 2019; IPCC 2022a; GCRP 2018a). Climate change is expected to exacerbate some existing health threats and create new challenges, and more people could be exposed (GCRP 2018a). At the same time, climate

---

change could decrease the capacity of health systems to manage changes in health outcomes due to climate shifts.

### ***Observed and Projected Climate Impacts***

Health impacts associated with climate-related changes in exposure to extreme events (e.g., floods, droughts, heatwaves, severe storms) include death, injury, illness, or exacerbation of underlying medical conditions. Climate change will increase exposure risk in some regions of the United States due to projected increases in frequency and intensity of drought, wildfires, and flooding related to extreme precipitation, rising temperatures, and hurricanes (EPA 2021d).

Many types of extreme events related to climate change cause disruption to infrastructure—including power; heating, ventilation, and air conditioning systems; water; transportation; and communication systems—that are essential to maintaining access to health care and emergency response services that safeguard human health (EPA 2021d; GCRP 2016; IPCC 2022a). The damage caused by extreme events can disrupt transportation and access to health services, which exacerbates health conditions of those chronically sick (GCRP 2016).

Across climate risks, those experiencing discrimination, low-income populations, some communities of color, and older adults and children often experience disproportionate health impacts (Ebi et al. 2018; IPCC 2022a; GCRP 2018a). Populations with greater health and social vulnerability often have less access to resources, information, institutions, or other factors that could help avoid or prepare for the health risks of climate change (Ebi et al. 2018; IPCC 2022a; GCRP 2018a).

### **Extreme Temperature**

One direct way climate change is projected to affect human health is through increasing exposure to extreme heat, which is the leading source of weather-related deaths in the United States (Nahlik et al. 2017; Sailor et al. 2019). Hospital admissions and emergency room visits tend to increase during hot days with heat-related illnesses, including cardiovascular and respiratory complications, renal failure, electrolyte imbalance, and kidney stones (GCRP 2018a). These hospitalizations come at a monetary cost to patients, who are more likely to be adults over 65 years, African Americans, Asian Americans/Pacific Islanders, and women (Schmeltz et al. 2016; GCRP 2018a). Higher than usual temperatures can cause heat exhaustion and heat stroke, and exacerbate other cardiovascular and pulmonary conditions (Mora et al. 2017; Tianqi et al. 2017 citing Borden and Cutter 2008, Bouchama et al. 2007, and Wilker et al. 2012; IPCC 2022a).

Certain populations are more vulnerable to extreme heat events than others. In general, those with preexisting conditions are more vulnerable to heat-related illness (Kuehn and McCormick 2017). In all parts of the world, the youngest, oldest, and poorest members of society are most vulnerable to health impacts from heat and cold events (EPA 2021d; GCRP 2016). Pregnant women and their fetuses are particularly vulnerable to the impacts of heat exposure because their thermoregulatory abilities are limited. Increased heat events could increase preterm birth, decrease birth weights, and increase the rate of stillbirths (Kuehn and McCormick 2017).

Higher temperatures and humidity can create negative health outcomes for people engaging in physical activity, or for those who work outside (IPCC 2018, 2022a). Worker safety and productivity during the hottest days and months will be a greater challenge under a changing climate (IPCC 2018). Longer-duration heatwaves are expected to heavily affect workers already exposed to extreme temperatures;

for example, outdoor workers (in both urban and rural areas) and miners. Occupational heat strain in outdoor workers may manifest as dehydration, mild reduction in kidney function, fatigue, dizziness, confusion, reduced brain function, loss of concentration, and discomfort (IPCC 2022a).

Certain geographic areas are more likely to experience damaging heat events. For example, the risk of heatwaves will be higher in cities as a result of the urban heat island effect (IPCC 2018, 2022a; GCRP 2018a). Additionally, increased mortality from extreme heat exposure will be more marked in regions that are currently warmer and poorer, particularly around the equator (Gasparrini et al. 2017; Mora et al. 2017).

With 1.5°C (2.7°F) of warming, twice as many megacities will be exposed to heat stress, which would expose approximately 350 million additional people to dangerous heatwave conditions by 2050 (IPCC 2018). It is projected that at a global scale, future exposure to heatwaves increases from approximately 15 million person-days in the current period to 170 billion person-days under business-as-usual emissions scenario (SSP2-4.5) and substantially higher to 535 billion person-days under a high emissions scenario (SSP5-8.5) (IPCC 2022a).

The reduction in cold-related deaths has not been studied as thoroughly as heat-related deaths, although such events have become less frequent and intense, and they are expected to continue to decrease (GCRP 2016). Warming associated with climate change could contribute to a decline in cold-related deaths, but evidence suggests that the impacts from extreme heat events greatly outweigh any benefits from decreases in cold-related deaths (GCRP 2018a; EPA 2015d, 2021d; IPCC 2022a citing Aboubakri et al. 2020, Achebak et al. 2020, Burkart et al. 2021, Rodrigues et al. 2020, and Weitensfelder and Moshammer 2020; Medina-Ramón and Schwartz 2007; GCRP 2018a citing Sarofim et al. 2016; Hajat et al. 2014; GCRP 2016 citing Mills et al. 2012, Deschênes and Greenstone 2011, Barreca 2012, and Honda et al. 2014).

Although extreme cold events are projected to become less frequent and severe under future warming, cold spells and cold waves may continue to threaten certain areas, especially in milder regions with larger temperature differences and less adaptive capacity to extreme cold (IPCC 2022a). Cold waves can cause adverse health impacts and premature deaths, in addition to threatening essential infrastructure and services (IPCC 2022a). For instance, the extreme cold temperatures experienced in Texas in February 2021 led to a significant increase in energy demand while adverse impacts on natural gas and electric power supply systems led to extensive power outages that left more than 4.5 million residents without power, resulted in 70 deaths, and economic losses estimated at \$196 billion (Zhiyuan et al. 2022).

### Air Quality

Although CO<sub>2</sub> emissions do not directly affect air quality, increased temperatures and related climate changes due to emissions of CO<sub>2</sub> and other GHGs could increase the formation of ozone and PM<sub>2.5</sub> and affect their dispersion and transport, affecting ozone and PM<sub>2.5</sub> concentrations. Climate change could increase ground-level concentrations of ozone or PM in some locations, degrading air quality and negatively affecting human health (Chapter 4, Section 4.1.1.1, *Health Effects of Criteria Pollutants*), as well as being associated with developmental problems such as childhood attention deficit hyperactivity disorder (Perera 2017 citing Newman et al. 2013; Perera et al. 2014). Under future warming, more people are projected to die from PM<sub>2.5</sub>- and ozone-attributable causes by end of century compared to 2000 (Fann et al. 2021). An additional 21,000 deaths are projected to occur due to PM<sub>2.5</sub> and an additional 4,100 deaths are projected to occur due to ozone (Fann et al. 2021).

Ozone formation is temperature-dependent and increases in ozone levels could result in more ozone-related mortality (IPCC 2018). Climate change may result in meteorological conditions more favorable for the formation of ozone, including higher temperatures, less relative humidity, and altered wind patterns (Jacob and Winner 2009; GCRP 2016). Ozone production could increase with rising temperatures, especially in urban areas (IPCC 2022a citing Archibald et al. 2020, Fu and Tian 2019, and Doherty et al. 2017). These climate-driven increases in ozone could cause premature deaths, hospital visits, lost school days, and acute respiratory symptoms (GCRP 2016; Silva et al. 2017).

As with ozone, climate change is expected to alter several meteorological factors that affect PM<sub>2.5</sub>, including precipitation patterns, wind patterns and atmospheric mixing, and humidity, although there is less consensus regarding the effects of meteorological changes on PM<sub>2.5</sub> than on ozone (Jacob and Winner 2009; GCRP 2016 citing Dawson et al. 2014). Because of the strong influence of changes in precipitation and atmospheric mixing on PM<sub>2.5</sub> levels and because of the high variability in projected changes to those variables, it is not yet clear whether climate change will lead to a net increase or decrease in PM<sub>2.5</sub> levels in the United States (GCRP 2016 citing Dawson et al. 2014, Fiore et al. 2012, Penrod et al. 2014, Tai et al. 2012, Val Martin et al. 2015, Dawson et al. 2009, and Trail et al. 2014). Overall, however, eastern, midwestern, and southern states are projected to experience degraded air quality associated with climate change (EPA 2015d; GCRP 2016).

Climate change can also affect air quality through an increasing number of wildfires and changing precipitation patterns. Wildfires produce PM pollutants and ozone precursors that diminish both air quality and human health (EPA 2021d; GCRP 2016; Reid et al. 2016, 2019). Exposure to PM pollutants and extreme heat are individually associated with negative health impacts but can also have synergistic impacts on human health, as evidenced by the record-setting wildfire season experienced by California in 2020, where an estimated 42 percent of the state's population simultaneously experienced hazardous smoke PM<sub>2.5</sub> and extreme temperatures at least once in that year (Rosenthal et al. 2022). Exposure to wildfire smoke has been linked to various adverse health impacts, including inflammation, reduced lung function, lung cancer, and mortality (UNEP and GRID-Arendal 2022; Burke et al. 2021 citing Casio 2018 and Reid et al. 2016). Wildfires can also cause adverse mental health impacts, such as post-traumatic stress disorder (UNEP and GRID-Arendal 2022).

Climate change could also affect air quality through changes in vegetative growth, increased summertime stagnation events, and increased absolute humidity (GCRP 2018a citing Leung and Gustafson 2005, Horton et al. 2014, Heald et al. 2008, and Lam et al. 2011). Further, climate change is projected to increase flooding in some locations both in the United States (GCRP 2017) and around the world (IPCC 2022a). Combined with higher air temperatures, this could foster the growth of fungi and molds, diminishing indoor air quality, particularly in impoverished communities (GCRP 2018a citing Fisk 2015, Fann et al. 2016, and Institute of Medicine 2011).

Increased temperatures and CO<sub>2</sub> concentrations can shift or extend plant growing seasons, including those of plants that produce allergens and pollen (EPA 2021d; GCRP 2018a citing Ziska et al. 2011 and Fann et al. 2016; Hjort et al. 2016). These effects already occur worldwide and are projected to continue with climate change (D'Amato et al. 2013; GCRP 2018a citing LaDeau and Clark 2006, Anenberg et al. 2017, Albertine et al. 2014, Singer et al. 2005, and EPA 2016; IPCC 2022a). Increases in pollen and other aeroallergens can exacerbate asthma and other health problems such as conjunctivitis and dermatitis (EPA 2021d; IPCC 2022a citing Beggs 2021, Ziska et al. 2019, Ziska 2020, and de Souza Hacon et al. 2019). Exposure to air pollutants such as increased ozone or PM levels could also exacerbate the

effects of aeroallergens (GCRP 2016 citing Cakmak et al. 2012). Increases in aeroallergens has also been known to reduce school and work productivity (GCRP 2016, 2018a).

### Water- and Food-Borne Pathogens

Climate—both temperature and precipitation—can influence the growth, survival, and persistence of water- and food-borne pathogens (EPA 2021d; IPCC 2022a). Also, changing weather patterns may shift the geographic range, seasonality, and intensity of climate-sensitive infectious disease transmission (IPCC 2018). For example, heavy rainfall and increased runoff promote the transmission of water-borne pathogens and diseases in recreational waters, shellfish-harvesting waters, and sources of drinking water with increased pathogens and toxic algal blooms (GCRP 2016, 2018a; EPA 2021d). Diarrheal disease rates are also linked to temperatures (IPCC 2022a). More frequent and intense rainfall and storm surge events could lead to combined sewer overflows that can contaminate water resources (GCRP 2018a; EPA 2021d; IPCC 2022a citing Howard et al. 2016, Khan et al. 2015, and Sherpa et al. 2014) and changes in streamflow rates can precede diarrheal disease outbreaks like salmonellosis and campylobacteriosis (GCRP 2018a citing Soneja et al. 2016 and Jiang et al. 2015; GCRP 2016). In general, heavy rainfall, flooding, and high temperatures are associated with higher rates of diarrheal disease (GCRP 2018a). Rising water temperatures could also increase the growth and abundance of pathogens in coastal environments that cause illnesses and deaths from both water contact and ingestion of raw or undercooked seafood. Changes in ocean pH may also increase virulent strains of pathogens prevalent in seafood, particularly because acidification can increase the proliferation of microbes that affect shellfish, whose immune responses and shells are weakened, making them more susceptible to infection (National Institutes of Health [NIH] 2010). Higher temperatures are expected to increase *Vibrio*, a temperature-sensitive and dangerous marine pathogen (GCRP 2018a; Muhling et al. 2017). Climate-change-induced drought may increase the spread of pests and mold that can produce toxins dangerous to consumers (IPCC 2022a; NIH 2010 citing Gregory et al. 2009). Similar to other climate change health impacts, children and the elderly are most vulnerable to serious health consequences from water- and food-borne diseases that could be affected by climate change (GCRP 2018a; IPCC 2022a).

### Vector-Borne Diseases

Climate change, particularly changes in temperatures, could change the range, abundance, and disease-carrying ability of disease vectors such as mosquitoes or ticks (GCRP 2016, 2018a; EPA 2021d; IPCC 2022a; Bouchard et al. 2019). This, in turn, could affect the prevalence and geographic distribution of diseases such as Rocky Mountain spotted fever, plague, tularemia, malaria, dengue fever, chikungunya virus, Lyme disease, West Nile virus, and Zika virus in human populations (Watts et al. 2017; GCRP 2018a citing Centers for Disease Control and Prevention [CDC] 2017a, CDC 2017b, Klempa 2009, Erickson et al. 2012, Brown et al. 2013, Roach et al. 2017, Beard et al. 2016, and Washington State Department of Health 2018). Some of these changes are already occurring, although the interactions between climate changes and actual disease incidence are complex and multifaceted (Altizer et al. 2013; Deichstetter 2017).

### Mental Health

Climate change can influence mental health. People can experience adverse mental health outcomes and social impacts from the threat of climate change, the perceived direct experience of climate change, and changes to the local environment (EPA 2021d). Climate change is associated with mental health consequences ranging from stress to clinical disorders such as anxiety, depression, post-traumatic stress disorder, and thoughts and acts of suicide (GCRP 2018a; Burke et al. 2018; Khafaie et al. 2019). Extreme

weather conditions can increase stress population-wide, which can exacerbate preexisting mental health problems and even cause such conditions (EPA 2021d; IPCC 2022a citing Berry et al. 2010, Cianconi et al. 2020, Clayton et al. 2017, Ruzskiewicz et al. 2019, and Bromet et al. 2017). For example, individuals experiencing loss due to flood, wildfires, extreme storms report high levels of depression, anxiety, and post-traumatic stress disorder, which could persist for years after the event (GCRP 2018a; Belova et al. 2022). Children, the elderly, women, people with preexisting mental illness, the economically disadvantaged, Indigenous communities, people experiencing homelessness, and first responders are at higher risk for distress and adverse mental health consequences from exposure to climate-related disasters (GCRP 2018a; EPA 2021d; GCRP 2016 citing Osofsky et al. 2011 and Schulte et al. 2016). Recent research estimates that an increase of 1 to 6°C (1.8 to 10.8°F) of warming of mean U.S. average temperatures could increase the annual U.S. suicide rate by 0.7 to 4.1 percent (Belova et al. 2022).

Environmentally motivated migration and displacement may lead to disruption of social ties and community bonds, which may negatively affect mental health, for both those displaced and those who stay behind (Torres and Casey 2017; IPCC 2022a). Stress, induced by climate change or other factors, can also result in pregnancy-related problems such as preterm birth, low birth weight, and maternal complications (Harville et al. 2009; GCRP 2018a citing Dodgen et al. 2016, Gamble et al. 2016, Sarofim et al. 2016, Ngo and Horton 2016, and Ha et al. 2017; GCRP 2016 citing Sheffield and Landrigan 2011; Rylander et al. 2013). Heat can also affect mental health and has been known to increase aggressive behaviors, in addition to increasing suicide rates, dementia, and problems for patients with schizophrenia and depression (GCRP 2018a; EPA 2021d; GCRP 2016 citing Ruuhela et al. 2009, Dixon et al. 2007, Qi et al. 2009, and Preti et al. 2007).

### Transportation-Safety Impacts

Climate change can also indirectly affect health by damaging or disrupting essential infrastructure and services, such as transportation. Increasing temperatures and extreme events are already adversely affecting transportation assets across all modes and will continue to do so under future climate change (GCRP 2018a). For instance, high temperatures and heatwaves can threaten the health of roadworkers and consequently reduce construction hours and productivity (GCRP 2018a). Additionally, extreme heat can increase the risk of road accidents due to overheating of vehicles, tire shredding, and road buckling (GCRP 2018a). Extreme precipitation and flooding in both coastal and inland regions are progressively reducing the functionality of roads, bridges, and railways, causing congestion, damaging infrastructure, and increasing accident risk (GCRP 2018a). Extreme events can disrupt access to essential services and health care by causing longer response times for first responders and emergency workers (GCRP 2018a). Transportation safety impacts will disproportionately affect vulnerable populations, especially those in more remote areas who rely heavily on public transportation. Insufficient access to reliable and safe transportation can adversely affect both mobility and economic vitality, which can cause stress and mental health impacts (GCRP 2018a).

### Other Human Health Impacts

Climate change alters temperature, precipitation, and cloud cover, which can affect sun exposure behavior and may change the risk of ultraviolet (UV) ray-related health outcomes such as melanoma cases in outdoor workers (IPCC 2022a citing Modenese et al. 2018).

Contamination of drinking water caused by incidences of wildfires, droughts, and heavy rain can contribute to elevated levels of heavy metals (lead, mercury, cadmium, and chromium), pesticides, and

pharmaceuticals, which can increase human exposure to toxic compounds (IPCC 2022a). Increase in heavy rainfall and flooding can enhance runoff and increase the leaching of heavy metals into water systems, especially when sewage treatment plants are overwhelmed by runoff (IPCC 2022a). Ocean warming can facilitate the formation of methylmercury, the subsequent uptake of which by fish and marine food sources can affect the health of populations consuming them (IPCC 2022a). Studies have also shown that the combined impacts of climate change and arsenic in paddy fields can increase arsenic content in rice (IPCC 2022a citing Muehe et al. 2019).

Research is emerging on the role of climate change in increasing risks of pandemics like COVID-19. Shifts in wildlife range, human exploitation of wildlife, and loss of wildlife habitat quality have increased the opportunity for pathogens to spread from wildlife to human populations; climate change has contributed to this increased risk by driving animal and human migrations (IPCC 2022a).

### **Adaptation**

Many observed and projected risks for human health can be reduced or potentially avoided through timely, proactive and effective adaptation (*high confidence*) (IPCC 2022a). Current adaptation measures in the health sector have mostly been incremental;<sup>67</sup> for example, focusing on improvements to basic public health and health care services, such as vaccination programs and post-disaster initiatives (IPCC 2022a). However, incremental changes to policies and strategies have proven largely insufficient to reduce health risks from climate change. As risks to human health continue to increase under future warming, transformational adaptation aimed at building climate-resilient and environmentally sustainable health systems will become increasingly necessary (IPCC 2022a).

The public health community has identified several potential adaptation strategies to reduce the risks to human health from climate change. In the United States, the CDC has established the Building Resilience against Climate Effects Framework, which can help health officials assess how climate impacts could affect disease burdens and develop a Climate and Health Adaptation Plan (CDC 2022). The framework aligns with the Climate-Ready States and Cities Initiative, which provides grants and technical assistance to state and local health departments to prepare for and respond to health risks from climate change. The program provides resources for states, cities, and municipalities to develop their own climate and health adaptation plans, including concept documents, toolkits, webinars, and data resources (CDC 2022).

At the state level, governments can conduct vulnerability and adaptation assessments, develop emergency response plans for climate events, develop climate-proof health care infrastructure, and integrate surveillance systems for infectious disease (IPCC 2018).

In terms of specific adaptation measures, early warning programs can be cost-effective ways to reduce human health impacts from extreme weather events (GCRP 2018a citing Lowe et al. 2016, Semenza 2015, and Worrall et al. 2008). Heatwave early-warning systems can also be used to reduce injuries, morbidity, and mortality due to heatwaves (IPCC 2018, 2022a). A local adaptation strategy may include opening a community cooling center during heatwaves to accommodate vulnerable and at-risk populations (Nayak et al. 2017). In the long term, strategies to reduce the urban heat island effect such

---

<sup>67</sup> IPCC defines *incremental adaptation* as measures that maintain the essence and integrity of a system or process at a given scale. Incremental adaptations are understood as extensions of actions and behaviors that already reduce the losses or enhance the benefits of natural variations in extreme weather or climate events. On the other hand, transformational adaptation is understood to change the fundamental attributes of a socio-ecological system in anticipation of climate change and its impacts (IPCC 2022a).

as cool roofs and increased green space can reduce health risks from extreme heat (GCRP 2018a citing Gronlund et al. 2015 and Klein Rosenthal et al. 2014; Boumans et al. 2014; McDonald et al. 2016). GHG reduction policies can also create co-benefits for air pollution by reducing pollutants, such as PM, SO<sub>2</sub>, nitrogen dioxide, and other harmful pollutants (IPCC 2018). Thus, mitigation strategies can have health benefits by improving air quality and promoting active transportation, which can reduce rates of obesity, diabetes, and heart disease (GCRP 2018a citing Panno et al. 2017, Maizlish et al. 2013, and Haines et al. 2009).

### **E.5.2.8 Human Security**

This section provides an overview of the recent findings regarding observed and projected impacts of climate change on human security in the United States and globally. IPCC defines human security in the context of climate change as “a condition that exists when the vital core of human lives is protected, and when people have the freedom and capacity to live with dignity” (IPCC 2022a). As there are multiple drivers of human security, it can be difficult to establish direct causation between climate change and impacts on human security. Rather than directly causing conflict, climate stress could drive changes in commodity prices or food and water insecurity, which are drivers of conflict (GCRP 2018a). Overall, the research literature finds that climate change has negative impacts on various dimensions of human security, including livelihoods, food, water, cultures, migration, and conflict. However, some dimensions of human security are driven more by economic and social forces rather than by climate change (IPCC 2022a). According to the U.S. Department of Defense (DOD), climate change may have far-reaching impacts on existing problems, such as poverty, social tensions, environmental degradation, ineffectual leadership, and weak political institutions, both nationally and internationally (DOD 2015, 2021).<sup>68</sup>

#### **Observed and Projected Climate Impacts**

Human security includes access to food, clean water, shelter, and employment, as well as avoidance of direct risks to health. Climate change poses significant risks to all of these aspects and can thereby threaten the human security of individuals or communities (IPCC 2022a). Even with an increase of approximately 1.5°C (2.7°F) by 2030, climate change will be a *poverty multiplier* that increases levels of poverty and the number of people living in poverty (IPCC 2018 citing Hallegatte et al. 2016 and Hallegatte and Rozenberg 2017). In particular, climate change will affect those whose livelihoods depend on natural resources (Brzoska and Frohlich 2015; Reyner et al. 2017). There are well-documented impacts of climate variability and change on agricultural productivity and food insecurity, water stress and scarcity, and destruction of property and residence (IPCC 2022a). Populations that are most at risk of food insecurity include the urban poor and the rural and Indigenous communities whose livelihoods are highly dependent upon natural resources (IPCC 2022a citing Martin Shields and Stojetz 2019 and FAO et al. 2018; GCRP 2018a).

Around the world, it is increasingly challenging for Indigenous communities to maintain cultures, livelihoods, and traditional food sources in the face of climate change (IPCC 2022a citing Jaakkola et al. 2018, Nilsson et al. 2011, Furberg et al. 2011, Amstislavski et al. 2013, Zavaleta et al. 2018, Akande et al. 2021, Bogdanova et al. 2021, and Bryson et al. 2021). The impacts of climate change are expected to be more significant both in places where Indigenous people live and on traditional ecological knowledge (IPCC 2018 citing Olsson et al. 2014). Many studies indicate that further significant changes in the

---

<sup>68</sup> Sources cited throughout this section may use other terms that fall within the concept of *human security* (e.g., economic and livelihood security, national security, food security). For simplicity, *human security* is used in throughout this section.

natural resource base would negatively affect Indigenous cultures, particularly if people are confined to particular territories created by treaties; if natural resources are lost within that territory, that is a permanent loss to the tribe and its culture (IPCC 2022a; GCRP 2018a). For example, climate change is causing changes in the range and abundance of culturally important plant and animal species, reducing the availability of and access to traditional foods, and increasing damage to tribal homes and cultural sites (GCRP 2018a citing Hambrecht and Rockman 2017). Ultimately, this could make life on ancestral lands untenable (IPCC 2018). Climate change can also cause loss of land and displacement, such as in small island nations or coastal communities, which have well-documented negative cultural and well-being impacts (IPCC 2022a).

Studies show that when planned resettlement and relocation initiatives are implemented without adequate participation of those affected, relocated communities can experience significant financial and emotional distress due to disruptions to cultural and spiritual bonds to place and livelihoods (IPCC 2022a citing Neef et al. 2018, Bertana 2020, McMichael and Katonivualiku 2020, and McMichael et al. 2021). Lack of involvement in formal government decision-making over resources also decreases the resilience of Indigenous peoples and their cultures to climate change impacts (GCRP 2018a; IPCC 2022a citing Frye and Parker 2016, Anderson and Leonard 2016, Frye 2012, Singletary et al. 2016, Shoemaker 2015, and Miller 2016).

Climate change is expected to increase internal migration and displacement, in part due to extreme events or long-term environmental changes (IPCC 2022a citing Thomas et al. 2020 and van der Geest et al. 2020). However, the causation and extent of this risk is hard to determine due to the complexity of migration decisions (IPCC 2022a). An increase in the incidence or severity of extreme events due to climate change will directly increase the risks of displacement and amplify its impacts on human security (IPCC 2022a). Projections indicate that 4.2 million Americans could be at risk with 3 feet of sea-level rise, and 13.1 million people with 6 feet of sea-level rise, which could drive mass migration and societal disruption (Hauer 2017; Hauer et al. 2016). In the past, major extreme weather events have led to significant population displacement (IPCC 2022a). For example, after Hurricane Katrina, refugees from coastal areas spread to all 50 states, which resulted in economic and social costs around the country (GCRP 2018a).

Following rapid-onset events such as floods or storms, such displacement is usually short-term (Brzoska and Frohlich 2015). Voluntary migration often emerges as an alternative when other forms of adaptation are insufficient, and while temporary (or seasonal) migration is frequently used as a risk reduction strategy by rural households to cope with climate variability, permanent migration is less common, especially when the whole household relocates (IPCC 2022a citing Afifi et al. 2016, Call et al. 2017, Pigué et al. 2018, Borderon et al. 2019, Cattaneo et al. 2019, Hoffmann et al. 2020, Lopez-i-Gelats et al. 2015, Lu et al. 2016, and Kaczan and Orgill-Meyer 2020).

Climate-driven migration outside of the United States could have implications for human security, either due to immigrants to the United States or instability abroad. For example, there could be significant population displacement in the tropics due to warming. Tropical populations may have to move more than 1,000 kilometers by the end of the century, which could lead to a concentration of displaced persons on the margins, contributing to higher population densities in destination areas (IPCC 2018 citing Hsiang and Sobel 2016). Some of these refugees could come to the United States. For example, the United States granted Temporary Protected Status to 57,000 Honduran and 2,550 Nicaraguan nationals after Hurricane Mitch (GCRP 2018a).

Long-term changes in climate conditions, such as droughts or land degradation, have greater potential to result in permanent migration (Brzoska and Frohlich 2015). For example, higher temperatures have contributed to outmigration in 163 countries, specifically for those dependent on agriculture (IPCC 2018 citing Cai et al. 2016). According to the International Migration Database of the OECD, a 1°C (1.8°F) increase in temperature contributed to a 1.9 percent increase in migration flows from 142 countries moving to 19 receiving countries, and an additional increase in precipitation of 1 millimeter could increase migration by 0.5 percent (IPCC 2018 citing Backhaus et al. 2015).

Climate-change-induced mass migration threatens to adversely affect the humanitarian assistance requirements of the U.S. military, as well as strain its ability to respond to conflict (DOD 2015; NRC 2011b). Displacement affects human security by affecting housing, health, and economic outcomes (IPCC 2022a). A large influx of migrants can result in conflict and violence, especially if the refugees differ from the native population in ethnicity, nationality, and/or religion; have had previous conflicts with the receiving area; or want to settle long term (Brzoska and Frohlich 2015). In other cases, migration to more prosperous and resource-rich areas can dissolve conflicts (Brzoska and Frohlich 2015).

Conversely, extreme events can sometimes be associated with immobility, which—if involuntary—reflects inability, lack of agency and resource limitations, but can also be a deliberate choice by people to maintain livelihoods or due to social and cultural attachments to native places. Involuntary mobility can exacerbate inequality and increase future vulnerability of households to climate change impacts (IPCC 2022a). Involuntary displacement and migration that occurs among migrants who have low agency is often associated with poor outcomes for health, well-being, and socioeconomic security of migrants and fewer benefits to sending and receiving communities (*high confidence*) (IPCC 2022a).

The association between short-term warming and deviations in rainfall (including floods and droughts) with armed conflict is contested, with some studies finding a relationship while others find no relationship (IPCC 2022a citing Mach et al. 2019; Schleussner et al. 2016; Buhaug et al. 2015). Most studies find that climate change impacts on armed conflict are negligible in situations where other risk factors are extremely low, such as where per capita incomes are high or governance is effective and stable (IPCC 2022a). Many studies, however, argue that reduced availability and changes in the distribution of water, food, and arable land from a changing climate are factors prone to triggering violent conflicts (Brzoska and Frohlich 2015 citing Hsiang et al. 2013). Overall, compared to other socioeconomic factors, the influence of climate on conflicts is understood to be relatively weak (*high confidence*), and there is insufficient evidence at present to attribute armed conflict to anthropogenic climate change (IPCC 2022a). Some studies suggest a greater role for climate in influencing the dynamics of conflict than on being an initial trigger for conflict outbreak (IPCC 2022a).

The potential impacts of climate change on accelerating instability in volatile regions of the world have profound implications for national security of the United States. The DOD 2014 Quadrennial Defense Review indicates that the projected effects of climate change “... are threat multipliers that will aggravate stressors abroad such as poverty, environmental degradation, political instability, and social tensions—conditions that can enable terrorist activity and other forms of violence” (DOD 2015). For example, drought may increase the likelihood of sustained conflict, particularly for groups dependent on agricultural livelihoods, which are more vulnerable to climate change (IPCC 2018). With a 1°C (1.8°F) increase in temperature or a greater intensity of extreme rainfall events, intergroup conflicts could increase in frequency by 14 percent (IPCC 2018 citing Hsiang et al. 2013).

Climate change can compromise state integrity by affecting critical infrastructure, threatening territorial integrity, and increasing geopolitical rivalry (IPCC 2022a). Climate change impacts on critical

infrastructure will reduce the ability of countries to provide the economic and social services that are important to human security (IPCC 2022a citing Neumann and Hermans 2015, McLeman 2017, Barnett and McMichael 2018, Cattaneo et al. 2019, and Hoffmann et al. 2020). For example, extreme heat, storms and floods, and sea-level rise could directly affect military assets, such as roads, airport runways, and coastal infrastructure; disrupt supply chains; endanger personnel; inhibit training; and increase operating costs (GCRP 2018a). In addition, climate change can also affect military logistics, energy, water, and transportation systems, compromising the ability of the U.S. military to conduct its missions (NRC 2011b, 2013b; CNA Corporation 2014). Power outages and fuel shortages could affect the energy system, which could have cascading impacts on critical sectors that support the economy and national security (GCRP 2018a). Furthermore, the U.S. military could become overextended as it responds to extreme weather events and natural disasters at home and abroad, along with current or future national security threats (NRC 2011b; CNA Corporation 2014).

Sea-level rise, storm surge, and coastal erosion can threaten the territorial integrity of small island nations or countries with significant areas of soft low-lying coasts (IPCC 2022a). These changes can also have negative implications for navigation safety, port facilities, and coastal military bases (DOD 2015). Open access to resources and new shipping routes due to significant reductions in Arctic sea ice coverage could increase security concerns because of territorial and maritime disputes, if equitable arrangements between countries cannot be agreed to (IPCC 2022a; DOD 2015). A variety of maritime boundary disputes in the Arctic could be exacerbated by the increased accessibility of the region due to warmer temperatures (IPCC 2022a citing Drewniak et al. 2018; Smith and Stephenson 2013 citing Brigham 2011 and Elliot-Meisel 2009). Furthermore, nations bordering the Arctic maintain unresolved sea and economic zone disputes (Smith and Stephenson 2013 citing Liu and Kronbak 2010 and Gerhardt et al. 2010; NRC 2011b). Other transboundary impacts of climate change such as changing shared water resources and adverse impacts on food security can increase geopolitical rivalry between countries (IPCC 2022a). Additionally, climate change could increase tension and instability over energy supplies (CNA Corporation 2014).

### ***Adaptation***

Adaptation strategies can reduce vulnerability and thereby increase human security. Examples of adaptation measures to improve livelihoods and well-being include diversification of income-generating activities in agricultural and fishing systems, development of insurance systems, and provision of education for women. Integration of local and traditional knowledge is found to increase the effectiveness of adaptation strategies. Improvements in Indigenous peoples' entitlements and rights, as well as engagement of Indigenous peoples in decision-making, increase their social and cultural resilience to climate change (IPCC 2022a citing Nurse-Bray et al. 2020). There is not enough evidence on the effectiveness of migration and resettlement as adaptation. Poorly designed adaptation strategies can increase the risk of conflict and amplify vulnerabilities in certain populations if they exacerbate existing inequalities or grievances over resources (IPCC 2022a).

Local and traditional knowledge is a valuable source of information for adapting to climate change (IPCC 2022a; GCRP 2018). There is high agreement in the literature that the integration of local and traditional and scientific knowledge increases adaptive capacity (IPCC 2022a). Moreover, traditional knowledge helps create resilient food systems, and bolster health and well-being more generally (IPCC 2022a citing High Level Panel of Experts 2020, Bezner Kerr et al. 2021, International Panel of Experts on Sustainable Food Systems 2020, and Bourke et al. 2018). While being an important resource for adaptation, traditional knowledge alone may be insufficient to respond to rapidly changing ecological

conditions or unexpected or infrequent risks as the ability of Indigenous peoples to anticipate and respond to climate change is significantly affected by a host of economic, social, political, and legal factors that may constrain their abilities to cope and respond (GCRP 2018a). Limited access to traditional territory and resources, and limitations of current policies and funding mechanisms in considering unique circumstances of Indigenous communities pose barriers to effective adaptation (GCRP 2018a). For example, case studies from Africa indicate that opportunities for Indigenous people to apply traditional drought mitigation strategies through migration have been limited by factors such as competing land use, policies around environmental protection, and limited mobility posed by national borders (IPCC 2022a citing Mamo 2020). While adaptation is possible to avoid some losses of cultural assets and expressions, cultural integrity will still be compromised if climate change erodes livelihoods, sense of place, and traditional practices, undermining some of the benefits of the adaptation strategy (GCRP 2018a; IPCC 2022a).

### **E.5.2.9 Stratospheric Ozone**

This section presents a review of stratospheric ozone and describes how CO<sub>2</sub> and climate change are projected to affect stratospheric ozone concentrations. Ozone is a molecule consisting of three oxygen atoms. Ozone near Earth's surface is considered an air pollutant that causes respiratory problems in humans and adversely affects crop production and forest growth (Salawitch et al. 2019). Conversely, ozone in Earth's stratosphere acts as a shield to block UV rays from reaching Earth's surface (Salawitch et al. 2019; Ravishankara et al. 2008).<sup>69</sup> This part of the atmosphere is referred to as the *ozone layer*, and it provides some protection to humans and other organisms from exposure to biologically damaging UV rays that can cause skin cancer and other adverse impacts for humans and other organisms (Salawitch et al. 2019; Fahey et al. 2008; Figure E.5.2-1). The ozone layer occupies the lower part of the stratosphere, which begins approximately 6 to 10 miles above Earth's surface and extends up to about 30 miles above the Earth's surface, although this changes with latitude and time of year (NOAA 2008a).

---

<sup>69</sup> These height measurements defining the bottom and top of the stratosphere vary depending on location and time of year. Different studies might provide similar but not identical heights. The heights indicated for the stratosphere and the layers within the stratosphere are provided in this section as defined by each study.

Figure E.5.2-1. The Three Lowest Layers in Earth's Atmosphere and the Location of the Ozone Layer

Source: Hegglin et al. 2015  
mPa: microPascal

Ozone in the stratosphere is created when a diatomic oxygen molecule absorbs UV rays at wavelengths less than 240 nanometers, causing the molecule to dissociate into two very reactive free radicals that then each combine with an available diatomic oxygen molecule to create ozone (Salawitch et al. 2019). Through this process, heat is released, warming the surrounding environment. Once ozone is formed, it absorbs incoming UV rays with wavelengths from 220 to 330 nanometers (Salawitch et al. 2019). The concentration of ozone in the stratosphere is affected by many factors, including concentrations of ozone-depleting substances and other trace gases, atmospheric temperatures, transport of gases between the troposphere and the stratosphere, and transport within the stratosphere. Specifically, ozone is depleted in reactions that involve halogens, such as chlorine and bromine, which result from the decomposition of some halocarbons (Salawitch et al. 2019; GCRP 2017 citing World Meteorological Organization [WMO] 2014). Alterations to the carbon cycle, including climate-driven ecosystem changes, influence atmospheric concentrations of  $\text{CO}_2$  and  $\text{CH}_4$ . In turn, atmospheric aerosols affect clouds and precipitation rates, which change the removal rates, lifetimes, and abundance of the aerosols themselves (GCRP 2017 citing Nowack et al. 2015). Also, stratospheric ozone abundance can be affected by climate-driven circulation changes and longwave radiation feedbacks (GCRP 2017 citing Nowack et al. 2015).

IPCC reports it is *very likely* and *extremely likely* that anthropogenic contributions, particularly to GHGs and stratospheric ozone depletion, have led to the detectable tropospheric warming and related cooling in the lower stratosphere since 1979, respectively (IPCC 2021b). Satellite and ground observations demonstrated clearly that stratospheric ozone was decreasing in the 1980s. Global annual mean total ozone declined by about 3.5 percent during the 1980s and early 1990s, compared to the pre-ozone

depletion 1964 to 1980 average (IPCC 2021a). There is an international consensus that human-made ozone-depleting substances (e.g., gases emitted by air conditioners and aerosol sprays) are responsible (IPCC 2021a), which has prompted the establishment of international agreements to reduce the consumption and emissions of these substances (Salawitch et al. 2019; Langematz 2019). In response to these efforts, the rate of stratospheric ozone reduction has slowed. Although there are elements of uncertainty, total column stratospheric ozone concentrations outside of polar regions are projected to recover to pre-1980 levels around 2040 (Salawitch et al. 2019; WMO 2022).

Stratospheric ozone levels influence the surface climate in both the Northern and Southern Hemispheres. In the Northern Hemisphere, stratospheric ozone extremes over the Arctic contribute to spring surface temperatures, particularly linking low Arctic ozone in March with colder polar vortex and circulation anomalies (Ivy et al. 2017). March stratospheric ozone can be used as an indicator of spring climate in certain regions (Ivy et al. 2017). In the Southern Hemisphere, comparison of the 1979 to 2010 climate trends shows that stratospheric ozone depletion drives climate change (Li et al. 2016). Interactive chemistry causes cooling in the Antarctic lower stratosphere and acceleration of the circumpolar westerly winds (Li et al. 2016; IPCC 2021a). In turn, this affects overturning circulation in the Southern Ocean, leading to stronger ocean warming near the surface and increased ice melt around the Antarctic (Li et al. 2016).

Changes in stratospheric ozone influence the climate by affecting the atmosphere's temperature structure and circulation patterns (Salawitch et al. 2019; Ravishankara et al. 2008; IPCC 2021a). Conversely, climate change could aid in the recovery of stratospheric ozone. Although GHGs, including CO<sub>2</sub>, warm the troposphere (the lower layer of the atmosphere), this process cools the stratosphere (IPCC 2021a). Consequently, it slows the chemical reactions between stratospheric ozone and ozone-depleting substances, assisting in ozone recovery. Climate change could enhance atmospheric circulation patterns that affect stratospheric ozone concentrations, assisting in ozone recovery in the extra-tropics. However, for polar regions, cooling temperatures can increase winter polar stratospheric clouds, which are responsible for accelerated ozone depletion. Large ozone depletions continue to appear in spring, such as over Antarctica (also known as the ozone hole), and in the Arctic in particularly cold years (IPCC 2021a). In summary, reduced stratospheric ozone may contribute to climate change, while climate change has been projected to have a direct impact on stratospheric ozone recovery, although there are large elements of uncertainty in these projections.

### ***Human-Made Ozone-Depleting Substances and Other Trace Gases***

Until the mid-1990s, stratospheric ozone concentrations had been declining in response to increasing concentrations of human-made ozone-depleting substances (IPCC 2022a; WMO 2022). Since the year 2000, ozone has been slowly increasing in the upper stratosphere (Steinbrecht et al. 2017). Examples of ozone-depleting substances include CFCs and compounds containing chlorine and bromine (WMO 2022; IPCC 2022a; Ravishankara et al. 2008; Fahey and Hegglin 2011). These ozone-depleting substances are chemically inert near Earth's surface but decompose into very reactive species when exposed to UV radiation in the stratosphere.

In 1987, an international agreement, the Montreal Protocol on Substances that Deplete the Ozone Layer, was established to reduce the consumption and production of human-made ozone-depleting

substances to protect and heal the ozone layer and rebuild the ozone hole.<sup>70</sup> Subsequent agreements have followed that incorporate more stringent reductions of ozone-depleting substances and expand the scope to include additional chemical species that attack ozone. Some ozone-depleting substances such as CFCs are potent GHGs; therefore, reducing the emissions of these gases also reduces radiative forcing and hence reduces the heating of the atmosphere. However, HFCs were not included in the Montreal Protocol. While atmospheric abundance of CFCs has been decreasing in response to the mandates of the Montreal Protocol, HCFCs, which are replacements for CFCs and HFCs (which are replacements for HCFCs) have been found to be increasing (IPCC 2021a). HFCs contribute to anthropogenic climate change, and global mean abundance of major HFCs has increased since 2016 (WMO 2022). In 2016, the Kigali Amendment to the Montreal Protocol introduced a treaty on managing and phasing out HFCs (Hurwitz et al. 2016).

Increases in the emissions of other trace gases (e.g., CH<sub>4</sub>, N<sub>2</sub>O) and CO<sub>2</sub> also affect stratospheric ozone concentrations (WMO 2018, 2022). When CH<sub>4</sub> is oxidized by hydroxyl radicals in the stratosphere, it produces water and the methyl radical. Increases in stratospheric water lead to an increase in reactive molecules that assist in the reduction of ozone and an increase in polar stratospheric clouds that accelerate ozone depletion. Increases in N<sub>2</sub>O emissions cause a reduction of ozone in the upper stratosphere as N<sub>2</sub>O breaks down into reactive ozone-depleting species (WMO 2022).

### **Changes in Atmospheric Temperature**

Since the observational record began in the 1960s, global stratospheric temperatures have been decreasing in response to ozone depletion, increased tropospheric CO<sub>2</sub>, and changes in water vapor (WMO 2022; IPCC 2021a; Fahey et al. 2008). Natural concentrations of GHGs increase the warming in the troposphere by absorbing outgoing infrared radiation; increasing GHG concentrations in the troposphere traps more heat in the troposphere, which translates to less incoming heat into the stratosphere. In essence, as GHGs increase, the stratosphere is projected to cool. However, model simulations suggest reductions in ozone in the lower to middle stratosphere (13 to 24 miles) create a larger decrease in temperatures compared to the influence of GHGs (WMO 2022; IPCC 2021a; Fahey et al. 2008 citing Ramaswamy and Schwarzkopf 2002). In the upper stratosphere, both the reductions of ozone and the impact of GHGs can contribute significantly to stratospheric temperature decreases (IPCC 2021a). It is estimated that anthropogenic forcings has caused a cooling of approximately 2 to 3°C (3.6 to 5.4°F) in the upper stratosphere between 1979 and 2015 (IPCC 2021a).

The cooling temperatures in the stratosphere could slow the loss of ozone (WMO 2018; Reader et al. 2013) because the dominant reactions responsible for ozone loss slow as temperatures cool. For example, ozone in the upper stratosphere is projected to increase by 15 to 20 percent under a doubled CO<sub>2</sub> environment, and by 30 to 40 percent under a quadrupled CO<sub>2</sub> environment (Fahey et al. 2008 citing Jonsson et al. 2004; Chiodo et al. 2019). In the lower stratosphere, where day-night energy transport plays an important role both within the stratosphere and between the troposphere and stratosphere, cooling temperatures have less influence on ozone concentrations (except in the polar regions). Since 1993, ozone in the lower stratosphere above the Arctic has been greatly affected by cooling temperatures, as cooling has led to an increase in polar stratospheric clouds (WMO 2022; Fahey et al. 2008). Polar stratospheric clouds play a significant role in reducing ozone concentrations. Ozone

---

<sup>70</sup> Significant thinning in the ozone layer has been observed above the Antarctic since the spring of 1985, to such a degree it is termed the *ozone hole* (WMO 2018; Ravishankara et al. 2008). This location is particularly susceptible to ozone loss due to a combination of atmospheric circulation patterns and the buildup of ozone-depletion precursors during the dark winter months from June to September.

in the lower stratosphere above the Antarctic does not demonstrate such a significant response to cooling temperatures because this region already experiences temperatures cold enough to produce these clouds.

### ***Circulation and Transport Patterns***

The large-scale Brewer-Dobson circulation represents the transport between the troposphere and stratosphere: an upward flux of air from the troposphere to the stratosphere occurs in the tropics balanced by a downward flux of air in the extratropics (i.e., the middle latitudes that extend beyond the tropics). This circulation carries stratospheric ozone from the tropics poleward (IPCC 2021a). It is suggested that the ozone in the lower stratosphere has experienced an acceleration in this transport over the past century, particularly in the Northern Hemisphere—potentially explaining the larger increase in total atmospheric ozone per area (i.e., column ozone) observed in the Northern Hemisphere compared to the Southern Hemisphere (Reader et al. 2013). According to many chemistry-climate models and observational evidence, climate change is thought to accelerate the Brewer-Dobson circulation (IPCC 2021a), extending the decline of ozone levels in the tropical lower stratosphere through the 21st century (WMO 2022).

Models suggest that the reduction of ozone above Antarctica is responsible for strengthening the circulation of stratospheric circumpolar winds of the wintertime vortex (i.e., the establishment of the vortex leads to significant ozone loss in late winter/early spring) (Fahey et al. 2008 citing Gillet and Thompson 2003 and Thompson and Solomon 2002).<sup>71</sup> Observations have shown that these winds can extend through the troposphere to the surface, leading to cooling over most of Antarctica. These studies suggest changes in stratospheric ozone can affect surface climate parameters.

### ***Trends and Projections***

Observations of global ozone concentrations in the upper stratosphere have shown a strong and statistically significant decline of approximately 6 to 8 percent per decade from 1979 to the mid-1990s (WMO 2018; Pawson and Steinbrecht 2014). Observations of global ozone within the lower stratosphere demonstrate a slightly smaller but statistically significant decline of approximately 4 to 5 percent per decade from 1979 to the mid-1990s (WMO 2018). An updated study from 2000 to 2020 found that ozone outside of the polar regions increased in the upper stratosphere by about 1.1 to 1.6 percent per decade in the tropics and by 1.5 to 2.2 percent per decade in the mid latitudes (35 to 60 degrees) (WMO 2022). Models attribute about half of the observed upper stratospheric ozone increase after the year 2000 to the decline in ozone-depleting substances, and the other half to cooling of upper stratosphere that slows down ozone destruction cycles (IPCC 2022a). From 2000 to 2020 in the lower stratosphere, there is model- and observation-based evidence indicating a small decrease of about 1 to 2 percent per decade (WMO 2022); this deviates from previous studies that indicated no statistically significant change in the lower stratosphere for these years (Steinbrecht et al. 2017). Radiative forcing from stratospheric ozone changes over 1850 to 2011 is estimated to cause a slight radiative cooling of  $-0.02 \text{ W/m}^2$ , with an uncertainty of  $\pm 0.13 \text{ W/m}^2$  (WMO 2022).

---

<sup>71</sup> During the polar winter, a giant vortex with wind speeds exceeding 300 kilometers (186 miles) per hour can establish above the South Pole, acting like a barrier that accumulates ozone-depleting substances. In Antarctic springtime, temperatures begin to warm and the vortex dissipates. The ozone-depleting substances, now exposed to sunlight, release large amounts of reactive molecules that significantly reduce ozone concentrations (Fahey and Hegglin 2011).

Modeled projections for total column ozone (i.e., the total ozone within a column of air from Earth's surface to the top of the atmosphere) show that total column ozone returns to its 1980 value sooner for scenarios that assume larger emissions of GHGs than scenarios with smaller GHG emissions (WMO 2022). For middle-of-the-road scenario SSP2-4.5 the model ensemble suggests the northern mid-latitudes (35 to 60 degrees north) total column ozone will recover to 1980 levels around 2035, and the southern mid-latitudes (60 to 35 degrees south) total column ozone will recover around 2045 (WMO 2022). Overall, the recovery of near global mean ozone column to 1980 levels in the mid-latitudes (60 degrees south to 60 degrees north) is projected to occur around 2040 (WMO 2022). The Arctic recovery time to 1980 conditions is estimated to be slightly before mid-century (around 2045), while the Antarctic will regain 1980 concentrations shortly after mid-century (around 2065) (WMO 2022). The recovery is linked to impacts of climate that affect total column ozone, including increased formation of ozone in the mid- to upper stratosphere in response to cooling temperatures, accelerated ground-level ozone formation in the troposphere as it warms, and an accelerated Brewer-Dobson circulation increase in ozone transport in the lower stratosphere from the tropics to the mid-latitudes (WMO 2022).

In another study, doubled CO<sub>2</sub> concentrations simulated by 14 climate-change models project a 2 percent increase per decade in the annual mean troposphere-to-stratosphere exchange rate. This acceleration could affect long-lived gases such as CFCs, CH<sub>4</sub>, and N<sub>2</sub>O by reducing their lifetime and increasing their removal from the atmosphere. In addition, this could increase the vertical transport of ozone concentrations from the stratosphere to the troposphere over mid-latitude and polar regions (Fahey et al. 2008 citing Butchart and Scaife 2001).

#### ***E.5.2.10 Compound Events***

According to the IPCC, compound events consist of combinations of multiple drivers and hazards that contribute to societal or environmental risk (IPCC 2022a). While some compound events may involve individual components that cancel one another out, others may include components with additive or even multiplicative effects (GCRP 2017). Compound events can also have societal impacts even if they occur across separate regions; for example, droughts in multiple agricultural areas could have amplifying effects on food shortages (GCRP 2017).

The underlying probability of compound events occurring may increase because of climate change, as underlying climate variables shift (GCRP 2017). Examples of shifting underlying conditions that could contribute to compound event frequency or severity include higher temperatures (of both surface and sea), increased drought risk, increased overall precipitation, and changes to oceanic circulation patterns (Cook et al. 2015; GCRP 2017; Swain et al. 2016). Climate change could also facilitate the emergence of new types of compound events by combining previously unseen physical effects (GCRP 2017). An example of this is Hurricane Sandy, which was affected by sea-level rise, anomalously high temperatures, and a so-called "blocking ridge" around Greenland that steered the storm toward the mainland and may have been caused by reduced summer sea ice in the region (GCRP 2017).

The interconnectedness of the ocean and cryosphere can also lead to a type of compounding event called a cascade, where changes in one event trigger and increase the likelihood of secondary changes in different but connected elements of the system (IPCC 2022a citing IPCC 2019b). For example, enhanced melting and mass loss from ice sheets creates a huge flux of fresh water and iron to the ocean, which can, in turn, have dramatic effects on ocean productivity. Similarly, increasing ocean temperatures and sea level can affect ice shelf, ice sheet, and glacier stability because of the nonlinear response of ice melt, and calving, to ocean temperatures (IPCC 2022a). In this case, small increases in ocean

temperature have the potential to destabilize large sections of ice sheets and contribute to large sea-level rise changes (IPCC 2022a).

Compound events may also lead to limited recovery time that can have far reaching detrimental impacts for socio-ecological systems. For example, between 1998 and 2016, the Maldives Islands were affected by three major climate events, including the 1997–1998 ENSO event, the 2007 flood event, and the 2016 ENSO event (IPCC 2022a citing Morri et al. 2015). These successive events had cumulative devastating effects on the reef ecosystem and cascading effects on health and well-being, livelihoods, and the overall Maldives economy (IPCC 2022a).

The impact of climate change on the frequency and severity of compound events remains uncertain because many climate models only address certain aspects of the climate system and cannot forecast compound events that involve combined and complex events from different subsystems (GCRP 2017; AghaKouchak et al. 2014). This makes the risks posed by compound events undervalued in modeled estimates of future climate conditions (GCRP 2017; AghaKouchak et al. 2014 citing Gräler et al. 2013).

To the extent the Proposed Actions and alternatives would decrease the rate of CO<sub>2</sub> emissions relative to the No-Action Alternative, they would contribute to the general decreased risk of extreme compound events. While this rulemaking alone would not necessarily cause decreases in compound event frequency and severity from climate change, it would be one of many global actions that, together, could reduce these effects.

#### ***E.5.2.11 Tipping Points and Abrupt Climate Change***

*Tipping points* refer to thresholds in Earth systems that could be triggered by continued increases in the atmospheric concentration of GHGs, incremental increases in temperature, or other relatively small or gradual changes related to climate change. Earth systems that contain a tipping point exhibit large or accelerating changes or transitions to a new physical state, which are significantly different from the rates of change or states that have been exhibited in the past, when the tipping point is crossed. A recent study suggests that passing some tipping points may increase the likelihood of occurrence of other tipping points (McKay et al. 2022; Cai et al. 2016). The following discussion provides examples of tipping points in Earth systems.

Climate feedbacks can also drive tipping points in the climate system. Positive climate feedbacks amplify the impacts of anthropogenic emissions. For example, CO<sub>2</sub> emissions increase atmospheric temperatures, which increase the likelihood of wildfires that, in turn, release more CO<sub>2</sub> into the atmosphere (Mansoor et al. 2022; Liu et al. 2014). Climate feedbacks are complex and not always incorporated into future climate models and could lead to tipping points being crossed earlier than anticipated.

#### ***Atlantic Meridional Overturning Circulation***

AMOC is the northward flow of warm, salty water in the upper layers of the Atlantic Ocean coupled to the southward flow of colder water in the deep layers, which transports oceanic heat from low to high latitudes. If enough fresh water enters the North Atlantic (such as from melting sea ice or the Greenland ice sheet), the density-driven sinking of North Atlantic waters might be reduced or even stopped, as apparently occurred during the last glacial cycle (approximately 22,000 years ago) (IPCC 2021a; Katsman et al. 2018; Lenton et al. 2008 citing Stocker and Wright 1991). This is expected to reduce the northward flow of thermal energy in the Gulf Stream and result in less heat transport to the North

Atlantic. At the same time, reduced formation of very cold water may slow global ocean circulation, leading to impacts on global climate and ocean currents. A 2018 study indicates that these effects are underway, quantifying a 15 percent weakening since the mid-20th century and an overall weakening over the past 150 years (GCRP 2018a citing Caesar et al. 2018 and Thornalley et al. 2018).

IPCC reports it is *very likely* that the AMOC will weaken over the 21st century; further, it reports it is *likely* that there will be some decline in the AMOC by about 2050 regardless of the future GHG emissions trajectory, but the AMOC could also undergo fluctuations because of large natural internal variability (IPCC 2021a). IPCC also reports that it is *very unlikely* that the AMOC will experience an abrupt collapse before 2100 (*medium confidence*) (IPCC 2021a). Should an AMOC collapse occur, it is *very likely* to drive abrupt shifts in weather patterns and the water cycle, including a weakening of the African and Asian monsoons and strengthening of Southern Hemisphere monsoons (IPCC 2021a). There is *low confidence* in changes to the AMOC beyond the 21st century, but a large-scale collapse from large, sustained warming cannot be excluded (IPCC 2021a).

### **Greenland and West Antarctic Ice Sheets**

The sustained mass loss by ice sheets would cause a significant increase in sea level, and some part of the mass loss might be irreversible (IPCC 2021a). For example, under 2°C (3.6°F), about one-third of the Antarctic ice sheet and three-fifths of the Greenland ice sheet would be lost (GCRP 2018a citing Clark et al. 2016). There is *medium confidence* that a warming in the range of 3 to 5°C (5.4 to 9°F) would result in the near complete and irreversible loss of the Greenland ice sheet and the West Antarctic ice sheet over the next millennium or more (IPCC 2021a). The temperature range of 1.5 to 2°C (2.7 to 3.6°F) presents a moderate risk of triggering marine ice sheet instability in Antarctica (IPCC 2021a).

Of particular concern is the potential for abrupt increases in sea-level rise from rapid destabilization and ice loss from marine-based glaciers grounded on bedrock below sea level. Marine-based glaciers are prone to unground, destabilize, and rapidly contribute to sea-level rise due to a combination of mechanisms including basal melting, retreat, and acceleration. Climate change may drive abrupt and irreversible ice loss through an instability of marine-based sectors of the West Antarctic ice sheet in the absence of ice shelf buttressing. Several studies suggest that recent observations of sustained mass loss from large glaciers in Antarctica are consistent with the onset of this instability (Wild et al. 2022; Joughin et al. 2014; Rignot et al. 2014; IPCC 2021a). Some studies demonstrate the potential irreversibility of marine-based ice sheet loss and the presence of thresholds beyond which ice loss becomes self-sustaining, whereas other studies note glacier stability can be regained if ice shelves provide buttressing (IPCC 2021a; Mengel and Levermann 2014). Overall, there remains medium agreement for anthropogenic forcing of observed Antarctic mass balance changes and deep uncertainty regarding processes that may contribute to large increases in Antarctic mass loss under high GHG emissions (IPCC 2021a). The likelihood of rapid destabilization of the Greenland ice sheet this century is low, because the ice sheet periphery is not predominantly marine-based and most areas of deep water contact between ice sheets and the ocean are limited to narrow troughs and fjord systems that constrict ice discharge into ocean basins (NRC 2013a).

### **Arctic Sea Ice**

Since satellite observations of Arctic sea ice began in 1978, a significant decline in the extent of summer sea ice has been observed, with the record minimum extent—a decrease of more than 40 percent in September, i.e., the month when the minimum in the sea-ice extent typically occurs—recorded in 2012 (Figure E.5.2-2) (GCRP 2017; National Snow and Ice Data Center 2022a). IPCC (2021a) suggests that

anthropogenic influences have *very likely* contributed to these Arctic sea-ice losses since 1979, and that it is *very likely* that the Arctic sea-ice cover will continue to shrink and thin.

Rising temperatures are reducing ice volume and surface extent on land, lakes, and sea, with this loss of ice expected to continue. The Arctic Ocean is expected to become essentially ice free (i.e., where the ice extent is less than 1 million square kilometers) in September by the end of the 21st century under SSP2-4.5, SSP3-7.0, and SSP5-8.5 (IPCC 2021a). In the near term, it is *very likely* that September sea ice area minimums would continue to decrease (IPCC 2021a). The same projections also reveal decreasing March sea ice area maximums but to a lesser extent.

Figure E.5.2-2. Average Monthly Arctic Sea-Ice Extent (September 1979–2022)<sup>a</sup>

Notes:

<sup>a</sup> Ice extent for each September plotted as a time series based on the 1979 to 2022 data. The black line connects the ice extent data points and the trend line is plotted with a blue line.

Source: National Snow and Ice Data Center 2022b

Sea ice loss contributes to positive feedback by changing the albedo of the Arctic’s surface, affecting formation of ice the next winter (Riihela et al. 2021; GCRP 2018a citing Abe et al. 2016, Pedersen et al. 2016, and Post et al. 2013). Larger areas of open water in the Arctic during the summer will affect the Arctic climate, ecosystems, and human activities in the Northern Hemisphere; these impacts on the Arctic could potentially be large and irreversible. Less summer ice could disrupt the marine food cycle, alter the habitat of certain marine mammals, and exacerbate coastline erosion. For instance, sea ice is the primary habitat for polar bears. Polar bear movements are closely tied to the seasonal dynamics of sea-ice extent, and the loss of sea-ice habitat due to climate change is a primary threat to polar bears (IPCC 2022a; Pagano and Williams 2021; U.S. Fish and Wildlife Service 2016). Reductions in summer sea ice will also increase the navigability of Arctic waters, opening opportunities for shipping and economic

activities, but also creating new political and legal challenges among circumpolar nations (IPCC 2022a; NRC 2013a).

### ***Irreversibility of Anthropogenic Climate Change Resulting from Carbon Dioxide Emissions***

A large fraction of anthropogenic climate change resulting from CO<sub>2</sub> emissions (e.g., global mean temperature increase, decrease in ocean pH) is irreversible on a multi-century to millennial time scale, except in the case of a large net removal of CO<sub>2</sub> from the atmosphere over a sustained period (IPCC 2021a). Surface temperatures will remain approximately constant at elevated levels for many centuries after a complete cessation of net anthropogenic CO<sub>2</sub> emissions. Because of the long timescales of heat transfer from the ocean surface to depth, ocean warming will continue for centuries (IPCC 2021a). A recent study indicates that the Earth may be approaching an approximate 2°C (3.6°F) threshold after which the system as a whole would be locked into a rapid pathway toward much hotter conditions that would be accelerated by self-reinforcing feedbacks (Differbaugh and Barnes 2023; Steffen et al. 2018).

### ***Delaying Mitigation***

Several studies have shown that delaying mitigation of GHG emissions results in a greater accumulation of CO<sub>2</sub> in the atmosphere, thereby increasing the risk of crossing tipping points and triggering abrupt changes (IPCC 2021a; Anderson and Bows 2011; Friedlingstein et al. 2011; van Vuuren et al. 2011a, 2011b; Ranger et al. 2012). The studies speak to the delayed timing of reductions, which increases the overall cumulative amount of GHGs in the atmosphere. Consequently, regardless of future emissions rates, the greater amount of GHGs present in the atmosphere increases the likelihood of climatic changes and thus crossing certain tipping points.

### ***Increases in the Risk of Extinction for Marine and Terrestrial Species***

The rate of climate change is increasing the risk of extinction for a number of marine and terrestrial species (IPCC 2022a; NRC 2013a). Climate change can cause abrupt and irreversible extinctions through four known mechanisms (IPCC 2022a; NRC 2013a).

- Direct impacts from an abrupt event, such as flooding of an ecosystem through a combination of storm surge and sea-level rise.
- Incremental climatic changes that exceed a threshold beyond which a species enters decline; for example, pikas and ocean coral populations are close to physiological thermal limits.
- Adding stress to species in addition to nonclimatic pressures such as habitat fragmentation, overharvesting, and eutrophication.
- Biotic interactions, such as increases in disease or pests, loss of partner species that support a different species, or disruptions in food webs after the decline of a keystone species.

It is expected that some species will become extinct or fall below viable numbers in the next few decades (IPCC 2022a; NRC 2013a). IPCC states that there is *high confidence* that a large fraction of species faces increased extinction risk due to climate change during the 21st century and beyond (IPCC 2022a citing IPCC 2014).

### **Additional Tipping Points**

GCRP (2017) and NRC (2013a) indicate a number of other potential tipping points (Figure E.5.2-3) that are described in this section.

- **El-Niño-Southern Oscillation (ENSO).** It is *very likely* that regional rainfall variability due to ENSO will increase over this century, particularly in late 21st century (IPCC 2021a). In the United States, the rainfall variability associated with ENSO events will *likely* move eastward in the future, though some model disagreement exists (IPCC 2021a). Research indicates that the frequency of extreme El Niño events increases linearly with global mean temperature; under 1.5°C (2.7°F) of temperature warming, the number of extreme El Niño events could double (IPCC 2018 citing Wang et al. 2017). Ultimately, it is *likely* that extreme El Niño events, including rainfall exceeding the 5-millimeters-per-day threshold in the eastern equatorial Pacific, will increase in intensity (IPCC 2021a).
- **Amazon rainforest.** Deforestation, reductions in precipitation, a longer dry season, and increased summer temperature could contribute to accelerated forest dieback. Important additional stressors also include forest fires and human activity (e.g., land clearing) (IPCC 2022a; Lenton et al. 2008). In general, studies agree that future climate change increases the risk of the tropical Amazon forest being replaced by seasonal forest or savannah (IPCC 2022a). Overall, this region is projected to experience enhanced aridity (*high confidence*), and although the occurrence of a tipping point driving this ecosystem to an arid state in the 21st century is *unlikely*, continued deforestation and warming increase the probability of the tipping point (IPCC 2021a).
- **Boreal forest.** The dieback of boreal forest could result from a combination of increased heat stress and water stress, leading to decreased reproduction rates, increased disease vulnerability, and subsequent fire, as well as increased beetle infestations (IPCC 2022a). Although highly uncertain, studies suggest a global warming of 3°C (5.4°F) could be the threshold for loss of the boreal forest (Lenton et al. 2008). Models indicate that under a high emissions scenario (RCP8.5), even without water stress, additional heat could transition the boreal forests into a net CO<sub>2</sub> source (Helbig et al. 2017).

Figure E.5.2-3. Potential Tipping Points

Source: GCRP 2017 adapted from Lenton et al. 2008  
 km<sup>2</sup> = square kilometer

- **Release of methane hydrates and permafrost and tundra loss.** A catastrophic release of CH<sub>4</sub> to the atmosphere from clathrate hydrates<sup>72</sup> in the seabed and permafrost, and from northern high-latitude and tropical wetlands, has been identified as a potential cause of abrupt climate change (GCRP 2017). The size of the CH<sub>4</sub> hydrate reservoir in the Arctic is estimated to be between 500 and 3,000 Gt of carbon potentially being equivalent to 82,000 Gt CO<sub>2</sub> (assuming the hydrates are released in that state) (GCRP 2017). However, uncertainty exists in the sensitivity of these carbon reservoirs—as measured by the rate of carbon release from stored hydrates per unit of warming—to a changing climate (Mestdagh et al. 2017). These reserves will probably not reach the atmosphere in sufficient quantity to affect climate significantly over the next century (IPCC 2021a; GCRP 2017). Permafrost stores hold an additional estimated 1,300 to 1,600 Gt of carbon, about 5 to 15 percent of which is vulnerable to being released in the coming century (GCRP 2017 citing Schuur et al. 2015). It is very likely that emissions from thawing permafrost are amplifying carbon emissions and will continue to do so (IPCC 2021a; GCRP 2018a citing Schaefer et al. 2014, Koven et al. 2015, and Schuur et al. 2015; Yumashev et al. 2019). Past research warns that these tundra sources could cause an abrupt release of carbon, causing dramatic warming in the atmosphere (IPCC 2019a; Hansen et al. 2013; NRC 2013a), but more recent literature suggests that the most probable process is a gradual and prolonged release of carbon (Schuur et al. 2015; Mestdagh et al. 2017). These estimates of a slow emissions rate from permafrost and hydrates may be incorrect if anthropogenic GHG emissions cause the Earth to warm at a faster rate than anticipated (GCRP 2017).

To the extent that the Proposed Action and alternatives would decrease the rate of CO<sub>2</sub> emissions relative to the relevant No-Action Alternative, they could contribute to the marginal decrease or deceleration of reaching these tipping-point thresholds. Moreover, while this rulemaking alone would not cause sufficient CO<sub>2</sub> emissions reductions to avoid reaching the tipping-point thresholds, it would make substantial contributions in averting levels of abrupt and severe climate change when paired with many other global actions.

---

<sup>72</sup> Clathrate hydrates are *inclusion compounds* in which a hydrogen-bonded water framework—the host lattice—traps guest molecules (typically gases) within ice cages. Naturally occurring gas hydrate on Earth is primarily methane hydrate and forms under high pressure–low temperature conditions in the presence of sufficient methane (GCRP 2014 citing Brook et al. 2008).

## **APPENDIX G**

### **List of Preparers and Reviewers**

## APPENDIX G LIST OF PREPARERS AND REVIEWERS

### G.1 U.S. Department of Transportation

Table G.1-1 identifies the preparers, contributors, and reviewers in the U.S. Department of Transportation.

**Table G.1-1. U.S. Department of Transportation Preparers and Reviewers**

<b>Preparers</b>	
Vinay Nagabushana, Contracting Officer’s Representative, NHTSA	
	M.S., Mechanical Engineering, University of Texas at El Paso B.S., Mechanical Engineering, Bangalore University 26 years of experience in vehicle engineering and development of regulation in vehicle safety and fuel economy
Hannah Fish, Attorney Advisor, NHTSA	
	J.D., William & Mary Law School B.S., Environmental Studies, SUNY College of Environmental Science and Forestry 6.5 years of legal experience, including environmental law
Stephanie Walters, Attorney Advisor, NHTSA	
	J.D., University of Florida, Levin College of Law B.S.B.A., Marketing and Entrepreneurship, University of Florida Warrington College of Business 3.5 years of legal experience, including environmental law
Rebecca Blatnica, Environmental Protection Specialist, Volpe Center	
	M.S., Community and Regional Planning, University of Texas, Austin B.A., Geography and History, University of Texas, Austin 23 years of experience in NEPA compliance and analysis for transportation improvements
<b>Contributors and Reviewers</b>	
Joseph Bayer, Chief, Fuel Economy Division, NHTSA	
	M.S., Mechanical Engineering, University of Wisconsin, College of Engineering B.S., Mechanical Engineering, University of Wisconsin, College of Engineering 23 years of experience in automotive engineering, vehicle testing, performance and fuel economy development; 5 years of experience in vehicle fuel economy rulemaking
Aerin Kim, Attorney Advisor, NHTSA	
	J.D., George Mason University, Antonin Scalia Law School B.A., Psychology, Case Western Reserve University 3 years of legal experience, including environmental law
Andrew Eilbert, Physical Scientist, Volpe Center	
	M.S., Natural Resources and Environment, University of Michigan, Ann Arbor B.S., Physics, Brandeis University 14 years of experience in emissions and energy modeling, data science, and policy analysis; 7 years of experience in fuel economy and greenhouse gas rulemaking

**Appendix G List of Preparers and Reviewers**

Bentley Clinton, Economist, Volpe Center	
	Ph.D., Economics, University of Colorado, Boulder B.A., Economics and Mathematics, Bates College 12 years of experience in transportation, energy, and environmental economics and policy analysis
Eikar Lai, General Engineer, Volpe Center	
	B.E., Mechanical Engineering, City College of New York, City University of New York 7 years of experience in municipal vehicle fleet engineering development and acquisition; 6 years of experience in vehicle engine testing, design, manufacturing, and tooling; 1 year of experience in fuel economy rulemaking
Gonzalo Saenz, General Engineer, Volpe Center	
	M.B.A., Warrington College of Business, University of Florida B.S., Mechanical and Aerospace Engineering, University of Missouri, Columbia 9 years of experience in automotive and aerospace industry; 3 years of experience in fuel economy rulemaking
Mark Shaulov, IT Specialist, Volpe Center	
	B.S., Computer Science, Northeastern University 19 years of experience in fuel economy rulemaking
Alexis Zubrow, Physical Scientist, Volpe Center	
	M.S., Geography, University of Wisconsin, Madison A.B., Physics, Harvard University 21 years of experience in emissions, air quality, and environmental modeling and data analysis; 11 years of experience in environmental rulemaking
Don Pickrell, Chief Economist, Volpe Center	
	M.A. and Ph.D., Urban Planning, University of California, Los Angeles B.A., Economics and Mathematics, University of California, San Diego 46 years of experience in transportation economics, transportation policy, energy and environmental analysis, and benefit-cost evaluation
Katya Israel-Garcia, Economist, Volpe Center	
	B.A., Economics, Smith College 3 years of experience in fuel economy rulemaking

**G.2 Consultant Team**

The ICF Team supported NHTSA in preparing its environmental analyses and this EIS. Table G.2-1 identifies the consultant team and their contributions.

**Table G.2-1. Consultant Team**

<b>Project Management</b>	
Elizabeth Diller, Project Director	
	B.S., Environmental Science, University of Ulster at Coleraine, Northern Ireland 22 years of experience in the environmental field and 20 years of experience in the management, preparation, and review of NEPA documents

<b>Sarah Powers, Project Manager</b>	
	J.D., Boston University School of Law B.A., Astronomy and Physics, Boston University 15 years of legal and regulatory experience; 2 years of experience in macroeconomic analysis
<b>Debra Rogers, Project Manager</b>	
	M.B.A., University of North Carolina at Chapel Hill (Kenan Flagler Business School) B.S., Business Administration, Villanova University 25 years of experience managing NEPA processes
<b>Rob Greene, Deputy Project Manager</b>	
	M.B.A., Wilmington University B.A., Land Use Planning, Virginia Polytechnic Institute and State University 10 years of experience in management, preparation, and review of NEPA documents
<b>Libby Fortin, Project Coordinator</b>	
	B.A., Environmental Biology, Columbia University Over 6 years of experience supporting environmental efforts, including climate research; 3 years of experience supporting NEPA projects and permitting processes
<b>Sarah Baer, Project Coordinator</b>	
	B.S., Applied Geography, University of Louisville 7 years of experience in environmental science and NEPA processes
<b>Technical and Other Expertise</b>	
<b>Bikash Acharya, Climate Change Team</b>	
	M.S., Mechanical Engineering, University of Maryland B.S., Physics, Mathematical Economics, Applied Mathematics, Hampden-Sydney College 11 years of experience in climate change and sustainability analysis
<b>Hugh Arceneaux, Public Comments Team</b>	
	J.D., Tulane University Law School B.A., History, McGill University 5 years of experience in regulatory technical support
<b>Sneha Balakrishnan, Climate Change Team</b>	
	B.S., Botany, University of Delhi M.S., Environmental Studies, TERI School of Advanced Studies 7 years of experience in climate change and sustainability analysis
<b>Jenna Briscoe, Public Comments Team</b>	
	M.S., Environmental Science and Policy, Johns Hopkins University B.A., Environmental Studies, University of Maryland, Baltimore County 8 years of experience in technical document management and other policy and regulatory support
<b>Eva Burgos, Climate Change Team</b>	
	B.A., Physics and Music, University of Chicago 2 years of experience in climate change and sustainability analysis
<b>Noah Carpenter, Climate Change Team</b>	
	M.S., Meteorology, University of Oklahoma 3 years of experience in climate change and sustainability analysis

**Appendix G List of Preparers and Reviewers**

Ed Carr, Photochemical Analysis Lead	
	M.S., Atmospheric Science, University of Washington B.S., Meteorology, San Jose State University 41 years of experience in air quality and meteorological modeling
Mollie Carroll, Climate Change Team	
	B.A., Economics and Environmental Policy, Washington University in St. Louis 4 years of experience in climate change and sustainability analysis
David E. Coate, Other Environmental Impacts Team, Noise Analyst	
	M.S., Nuclear Engineering, Massachusetts Institute of Technology B.A., Mathematics, Physics, and Chemistry, Westminster College 40 years of experience in acoustics and vibration
David Ernst, Air Quality Team Lead	
	M.C.R.P., Environmental Policy, Harvard University B.S., Urban Systems Engineering, Brown University B.A., Ethics and Politics, Brown University 43 years of experience preparing air quality analyses for NEPA documents
Lizelle Espinosa, Administrative Record Team Lead	
	B.S., Government Administration, Christopher Newport University 17 years of experience in environmental impact assessment, policy analysis, environmental management, and regulatory compliance
Mason Fried, Climate Change Team	
	Ph.D., Geosciences, University of Texas, Austin M.S., Geology, Portland State University B.A., Geoscience, Hamilton College 12 years of experience in climate change and sustainability analysis
Anthony Ha, Publications Specialist	
	B.A., English Literature, Saint Mary's College of California 16 years of experience in document development, formatting, and technical methods for publications; MS Word expert
Kyle Herdegen, Climate Change Team	
	B.S., Environmental Science, Quantitative Energy, University of North Carolina 3 years of experience in climate change and sustainability analysis
Christopher Holder, Air Quality Team	
	M.S., Meteorology, North Carolina State University B.S., Meteorology, North Carolina State University 15 years of experience in hazardous air pollutant risk assessment, climate change impacts, and greenhouse gas emissions estimation
Shubh Jain, Climate Change Team	
	B.S., Environmental Geosciences, SUNY University at Buffalo 2 years of experience in climate change and sustainability analysis
Sophie Johnson, Climate Change Team	
	M.A., Climate and Society, Columbia University 4 years of experience in climate change and sustainability analysis

<b>Jason Jones, Energy Team</b>	
	Ph.D., Agricultural Economics, Texas A&M University 11 years of experience in environmental impact analysis
<b>Andrew Kindle, Energy Team</b>	
	Ph.D., Ecological Economics, Rensselaer Polytechnic Institute B.A., Economics and Political Science, Denison University 7 years of experience in environmental impact analysis
<b>Hannah Krauss, Climate Change Team</b>	
	M.S., Energy Policy and Climate, Johns Hopkins University B.A., Environmental Studies, Anthropology, St. Mary's College of Maryland 4 years of experience in climate change and sustainability analysis
<b>Alexander Lataille, Climate Change Lead</b>	
	B.S., Meteorology, Lyndon State College B.A., Global Studies, Lyndon State College 12 years of experience in climate change and sustainability analysis
<b>Dasha Latvis, Climate Change Team</b>	
	B.S., Supply Chain, Environmental Policy, Syracuse University 1 year of experience in climate change and sustainability analysis
<b>Alyssa Le, Other Environmental Impacts Team, Environmental Justice Analyst</b>	
	M.S., Geosciences, University of North Carolina, Wilmington B.S., Geology and Environmental Studies, Tufts University 7 years of experience in environmental regulatory analysis
<b>Jamie Liu, Other Environmental Impacts Team, Environmental Justice Analyst</b>	
	B.S., Environmental Science and minor in Environmental Engineering, University of California, Los Angeles 5 years of experience in climate change adaptation and resilience
<b>Deanna Lizas, Life-Cycle Assessment Lead and Climate Team</b>	
	M.E.M., Environmental Management, Yale University B.S., Environmental Science and Sociology, University of Michigan 15 years of experience in climate change, sustainability, and life-cycle materials management and energy analyses
<b>Kristen Lundstrom, Lead Editor</b>	
	B.A., English and Expository Writing, University of Washington 19 years of experience in editing and document management
<b>Audrey Magnuson, Climate Change Team</b>	
	B.A., Public Policy, Environmental Science and Policy, Duke University 1 year of experience in climate change and sustainability analysis
<b>Howard Marano, Climate Change Team</b>	
	M.P.P., Environmental Policy, George Washington University B.A., Government and International Politics, George Mason University 6 years of experience in climate change and sustainability analysis and climate change policy research

**Appendix G List of Preparers and Reviewers**

---

Christine McCrory, Lead Editor	
	Ph.D. candidate, Germanic Languages and Literatures, Washington University in St. Louis M.Phil., European Literature, Lincoln College, Oxford University, Oxford, England B.A., Anthropology and German, University of California, Berkeley 15 years of experience in editing and document management
Ryan McNamara, Climate Change Team	
	B.S., Economics, Duke University 1 year of experience in climate change and sustainability analysis
Claire Phillips, Climate Change Team	
	B.A., Environmental Studies and Government and Legal Studies, Bowdoin College 2 years of experience in environmental research and analysis with a focus on climate
Eliza Puritz, Life-Cycle Assessment and Climate Change Teams	
	J.D., George Washington University Law School, In Progress M.A., Energy and Environment, Boston University B.A., Environmental Science, Boston University 5 years of experience in climate change and sustainability analysis and energy, policy, and supply chain research
Ajo Rabemiarisoa, Life-Cycle Assessment Team	
	M.B.A., Environmental Sustainability, Wilmington University B.S., Chemical and Environmental Engineering, McGill University 9 years of experience in environmental engineering and sustainability; 2 years of experience building technical analysis and support documentation for life cycle assessment processes
Beth Rodehorst, Climate Change Team	
	M.E.M., Environmental Management, Yale University B.A., Environmental Sciences and Policy, Economics, Duke University 19 years of experience in climate change and sustainability analysis
Kimberly Stevens, Document Quality Control Lead	
	B.S., Geography, University of Utah 20 years of experience in preparation, management, and review of NEPA documents
Claire Trevisan, Climate Change Team	
	B.S., Civil and Environmental Engineering, University of Virginia 2 years of experience in climate change and sustainability analysis
John Venezia, Climate Change Senior Advisor	
	M.S., Environmental Science and Policy, Johns Hopkins University B.S., Biology and Environmental Science and Policy, Duke University 22 years of experience analyzing climate change, greenhouse gas emissions sources, and options for reducing emissions, focusing on the energy sector
Jenna Wheaton, Other Environmental Impacts Team, Historical and Cultural Resources Analyst	
	B.A., Anthropology, Mercyhurst University 10 years of experience in Section 106 and cultural resources analysis, as well as NEPA environmental permitting and planning

---

Abby Wiseman, Climate Change Team

---

	B.S., Engineering, Dartmouth University 1 year of experience in climate change and sustainability analysis
--	---

---

Carson Young, Climate Change Team

---

	B.S., Natural Resource Conservation, University of Florida B.A., Sustainability Studies, University of Florida 2 years of experience in climate change analysis, focusing on natural infrastructure, vulnerability, and risk assessment
--	---

# **APPENDIX H**

## **Distribution List**

## **APPENDIX H DISTRIBUTION LIST**

The CEQ NEPA implementing regulations (40 CFR 1502.20) specify requirements for transmitting an EIS. In accordance with those requirements, NHTSA is mailing notification of the availability of this EIS, as well as instructions on how to access it, to the elected officials and federally recognized Native American Tribes listed in this appendix. NHTSA is also sending an electronic notification of the availability of this EIS and instructions on how to access it to the federally recognized Native American Tribes listed in this appendix. NHTSA will send electronic notification to the agencies and other stakeholders listed in this appendix, which includes individuals who submitted comments in response to NHTSA’s August 2022 notice of intent to prepare an EIS<sup>1</sup> and provided an email address.

### **H.1 Federal Agencies**

- Advisory Council on Historic Preservation, Office of Federal Agency Programs
- Appalachian Regional Commission, Office of the General Counsel
- Argonne National Laboratory
- Armed Forces Retirement Home, Campus Operations
- Board of Governors of the Federal Reserve System, Engineering and Facilities
- Central Intelligence Agency, Environmental and Compliance Branch
- Committee for Purchase From People Who Are Blind or Severely Disabled/US AbilityOne Commission, Office of the General Counsel
- Consumer Product Safety Commission, Directorate for Economic Analysis
- Defense Nuclear Facilities Safety Board
- Delaware River Basin Commission
- Denali Commission
- Executive Office of the President, Office of Science and Technology Policy
- Export-Import Bank of the United States, Office of the Senior Counsel
- Export-Import Bank of the United States, Environmental and Social Policy and Review Program
- Farm Credit Administration, Office of Regulatory Policy
- Federal Communications Commission, Office of General Counsel
- Federal Communications Commission, Wireless Telecommunications Commission, Competition and Infrastructure Policy Division
- Federal Energy Regulatory Commission, Office of Energy Projects, Environmental Review and Permitting
- Federal Maritime Commission
- Federal Trade Commission, General Counsel for Litigation
- General Services Administration, Federal Permitting Improvement Steering Council

---

<sup>1</sup> Notice of Intent To Prepare an Environmental Impact Statement for Model Years 2027 and Beyond Corporate Average Fuel Economy Standards and Model Years 2029 and Beyond Heavy-Duty Pickup Trucks and Vans Vehicle Fuel Efficiency Improvement Program Standards, 87 FR 50386 (Aug. 16, 2022).

- General Services Administration, Public Buildings Service, Office of Portfolio Management and Customer Engagement
- International Boundary and Water Commission, U.S. & Mexico, Environmental Management Division
- International Trade Commission, Office of External Relations
- Marine Mammal Commission, Office of the General Counsel
- Millennium Challenge Corporation, Environmental and Social Assessment
- National Aeronautics and Space Administration, Environmental Management Division, Office of Strategic Infrastructure
- National Capital Planning Commission, Office of Urban Design and Plan Review Division
- National Credit Union Administration, Office of General Counsel, Division of Operations
- National Endowment for the Arts
- National Endowment for the Humanities
- National Indian Gaming Commission, Office of the General Counsel
- National Indian Gaming Commission, Office of the Chief of Staff
- National Institutes of Health, Division of Environmental Protection
- National Institute Standards and Technology, Office of Safety, Health, and Environment
- National Science Foundation, Office of the General Counsel
- Nuclear Regulatory Commission, Division of Fuel Cycle Safety, Safeguards, and Environmental Review
- Nuclear Regulatory Commission, Office of Nuclear Material Safety and Safeguards
- Oak Ridge National Laboratory
- Overseas Private Investment Corporation, Environmental Group
- Presidio Trust, NEPA Compliance
- Small Business Administration, Office of the General Counsel, Department of Litigation
- Social Security Administration, Office of Environmental Health and Occupational Safety
- Tennessee Valley Authority, Environmental Policy and Planning
- U.S. Access Board (Architectural and Transportation Barriers Compliance Board), Office of the General Counsel
- U.S. Agency for International Development
- U.S. Department of Agriculture, Agriculture Research Service, Natural Resources and Sustainable Agricultural Systems
- U.S. Department of Agriculture, Animal and Plant Health Inspection Service, Environmental Risk and Analysis Services
- U.S. Department of Agriculture, Farm Service Agency
- U.S. Department of Agriculture, National Institute of Food and Agriculture, Institute of Bioenergy, Climate, and Environment
- U.S. Department of Agriculture, Natural Resources Conservation Service, Ecological Services Division
- U.S. Department of Agriculture, Rural Development, Rural Utilities Service, Engineering and Environmental Staff

- U.S. Department of Agriculture, U.S. Forest Service—Ecosystem Management Coordination
- U.S. Department of Commerce, Economic Development Administration
- U.S. Department of Commerce, Energy and Environmental Law Division, Office of the General Counsel for Administration and Transactions
- U.S. Department of Commerce, First Responder Network Authority (FirstNet)
- U.S. Department of Commerce, National Oceanic and Atmospheric Administration, Environmental Review and Coordination Section, Office of the General Counsel
