**National Highway Traffic Safety
Administration**

APPENDIX A

Modeling Results Reported Separately by Vehicle Class

APPENDIX A MODELING RESULTS REPORTED SEPARATELY BY VEHICLE CLASS

A.1 Energy – Fuel Consumption Impacts Reported Separately for Passenger Cars and Light Trucks, and Heavy-Duty Pickup Trucks and Vans

Table A-1. Fuel Consumption and Decrease in Fuel Consumption by CAFE Standards Alternative (billion gasoline gallon equivalent total for calendar years 2022–2050)

	No-Action	PC2LT002	PC1LT3	PC2LT4	PC3LT5	PC6LT8
Fuel Consumption						
Cars	821	817	826	821	817	804
Light trucks	1,953	1,943	1,909	1,907	1,877	1,792
All light-duty vehicles	2,774	2,760	2,736	2,729	2,695	2,596
Decrease in Fuel Use Compared to the No-Action Alternative						
Cars	--	-4 (-1%)	+5 (+1%)	+0.2 (0%)	-4 (-1%)	-18 (-2%)
Light trucks	--	-10 (-1%)	-44 (-2%)	-46 (-2%)	-76 (-4%)	-161 (-8%)
All light-duty vehicles	--	-14 (-1%)	-39 (-1%)	-46 (-2%)	-80 (-3%)	-179 (-6%)

Notes: CAFE = Corporate Average Fuel Economy

Table A-2. Fuel Consumption and Decrease in Fuel Consumption by HDPUV FE Standards Alternative (billion gasoline gallon equivalent total for calendar years 2022–2050)

	No-Action	HDPUV4	HDPUV108	HDPUV10	HDPUV14
Fuel Consumption					
HDPUVs	419	419	415	412	402
Decrease in Fuel Use Compared to the No-Action Alternative					
HDPUVs	--	-0.3 (0%)	-4 (-1%)	-7 (-2%)	-17 (-4%)

Notes: HDPUV = heavy-duty pickup trucks and vans; FE = fuel efficiency

Table A-3. Fuel Consumption and Decrease in Fuel Consumption Cumulative Impacts of CAFE Standards and HDPUV FE Standards Alternatives (billion gasoline gallon equivalent total for calendar years 2022–2050)

	No-Action	PC1LT3 + HDPUV4	PC2LT002 + HDPUV108	PC6LT8 + HDPUV14
Fuel Consumption				
LD Vehicles + HDPUVs	3,193	3,178	3,174	2,955
Decrease in Fuel Use Compared to the No-Action Alternative				
LD Vehicles + HDPUVs	--	-15 (0%)	-19 (-1%)	-238 (-7%)

Notes: CAFE = Corporate Average Fuel Economy; HDPUV = heavy-duty pickup trucks and vans; FE = fuel efficiency

A.2 Air Quality – Nationwide Emissions Impacts Reported Separately for Passenger Cars and Light Trucks, and Heavy-Duty Pickup Trucks and Vans

Table A-4. Nationwide Criteria Pollutant Emissions (tons per year) in 2035 from Passenger Cars and Light Trucks by Emissions Component and Alternative, Direct and Indirect Impacts

Emissions Component	No-Action	PC2LT002	PC1LT3	PC2LT4	PC3LT5	PC6LT8
Carbon monoxide (CO)						
Cars tailpipe	2,118,522	2,117,993	2,128,013	2,126,902	2,129,705	2,120,680

^a The numbers in this table have been rounded for presentation purposes. As a result, the values might not reflect the exact difference between the values in all cases. This analysis was simulated using the same methodology as reported in Chapter 5, Section 5.3, *Analysis Methods*; however, it includes only emissions changes for light trucks.

^b Values reported as 0.0000 are more than zero but less than 0.0001. Values reported as -0.0000 are less than zero but more than -0.0001. Sea-level rise changes reported as 0.00 are more than zero but less than 0.01.

^c The values for global mean surface temperature and sea-level rise are relative to the average of the years 1986–2005.

CO₂ = carbon dioxide; °C = degrees Celsius; ppm = parts per million; cm = centimeters; SSP = Shared Socioeconomic Pathway

Tables showing CO₂ emissions and GHG emissions reductions (MMTCO₂) from the separate vehicle categories (passenger cars, light trucks, and HDPUVs) for purposes of the EIS’s cumulative impacts analysis are not presented here because this information was already presented in Chapter 5, Section 5.4.1, *Direct and Indirect Impacts on Greenhouse Gas Emissions and Climate Change* (Tables 5.4.1-1 through 5.4.1-4). CO₂ emissions and emissions reductions do not change between direct and indirect and cumulative impacts because they are not affected by the modeling reference scenario.

APPENDIX B

Responses to Public Comments

APPENDIX B RESPONSES TO PUBLIC COMMENTS

On July 28, 2023, the U.S. Department of Transportation (DOT) National Highway Traffic Safety Administration (NHTSA) released a proposed rule that would establish new Model Year (MY) 2027–2031 Corporate Average Fuel Economy (CAFE) standards for passenger cars and light trucks and set forth MY 2032 augural standards for those same vehicles. The rule also proposed to establish new fuel efficiency (FE) standards for MY 2030–2035 heavy-duty pickup trucks and vans (HDPUVs). With the notice of proposed rulemaking (NPRM), NHTSA issued a Draft Environmental Impact Statement (EIS) analyzing the environmental impacts of the proposed standards and reasonable alternative standards. The U.S. Environmental Protection Agency (EPA) published a Notice of Availability for NHTSA’s Draft EIS in the *Federal Register* on August 4, 2023; publication of the Notice of Availability in the *Federal Register* triggered the Draft EIS public comment period.¹ The Notice of Availability requested public input on the agency’s environmental analysis to Docket No. NHTSA-2022-0075 by October 4, 2023. On August 17, 2023, NHTSA’s NPRM was published in the *Federal Register* and it invited the public to submit comments on the NPRM on or before October 16, 2023 (via Docket No. NHTSA-2023-0022).² On September 29, 2023, NHTSA extended the comment period for the Draft EIS to October 16, 2023.³

NHTSA also held a virtual public hearing on the Draft EIS and the proposed rule on September 28, 2023. NHTSA received statements from approximately 130 individuals at the hearing. The agency received five comments in the docket for the Draft EIS and one comment in the rulemaking docket that addressed the Draft EIS.

In preparing this Final EIS, NHTSA reviewed comments received in EIS Docket No. NHTSA-2022-0075 and comments relevant to the EIS submitted to the NHTSA rulemaking docket (Docket No. NHTSA-2023-0022). NHTSA considered and evaluated all written and oral comments received during the public comment period in the preparation of this Final EIS. In this appendix to the Final EIS, NHTSA has quoted substantive excerpts from these comments and responded to the comments, as required by the National Environmental Policy Act (NEPA).⁴ The agency updated the EIS in response to comments on the rule and Draft EIS and based on updated information that became available after the agency issued the Draft EIS. The comments presented in this appendix (including all footnotes) are verbatim comment excerpts as written by the commenters.

NHTSA approached those comments submitted to the EIS and rulemaking dockets that were not substantive to specific aspects of the EIS as follows:

- NHTSA received comments directly addressing or otherwise related to the proposed rule, Technical Support Document (TSD), or Preliminary Regulatory Impact Analysis under the rulemaking docket (NHTSA-2023-0022) and the Draft EIS docket (NHTSA-2022-0075). Topics of these comments included technology cost and effectiveness, economic impacts of the rule, harmonization of the NHTSA and EPA rules, balancing the Energy Policy and Conservation Act of 1975 (EPCA) statutory criteria, and the underlying assumptions in them. NHTSA has reviewed all of the comments, and in

¹ *Environmental Impact Statements; Notice of Availability*, 88 FR 51812 (Aug. 4, 2023).

² *Corporate Average Fuel Economy Standards for Passenger Cars and Light Trucks for Model Years 2027–2032 and Fuel Efficiency Standards for Heavy-Duty Pickup Trucks and Vans for Model Years 2030–2035; Notice of Proposed Rulemaking*, 88 FR 56128 (Aug. 17, 2023).

³ *Environmental Impact Statements; Notice of Availability*, 88 FR 67277 (Sept. 29, 2023).

⁴ 40 CFR § 1503.4.

this appendix, NHTSA includes and addresses only those comments (or portions of those comments) considered substantive to the Draft EIS. NHTSA addresses substantive comments that concern the rule but that are not related to the EIS in the preamble to the final rule and its associated documents in the public docket.

- NHTSA received oral and written comments stating either general support for or general opposition to the proposed rule. NHTSA appreciates those comments, but because they do not raise specific issues or concerns pertaining to the EIS, this appendix does not respond to those comments. This appendix responds to comments specific to the EIS or to those that substantively address EIS analytical methods or approaches.

Written comments submitted to NHTSA and the virtual public hearing transcripts are part of the administrative record and are available on the Federal Docket at <http://www.regulations.gov>, Reference Docket No.: NHTSA-2022-0075 (Draft EIS) and NHTSA-2023-0022 (rulemaking).

Table B-1 lists the topics addressed in this appendix. Section B.1, *Proposed Action and Alternatives and Analysis Methods*, through Section B.7, *Other Comments*, provide relevant comments on the Draft EIS and the proposed rule and NHTSA’s responses to those comments.

Table B-1. Outline of Issues Raised in Public Comments on the Draft EIS

B.1 Proposed Action and Alternatives and Analysis Methods

B.1.1 No-Action Alternatives and Baselines

Comment

Comment Number: NHTSA-2022-0075-0032

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

A. None of the proposed alternatives for passenger cars and light-duty trucks are reasonable as they are based on an illegal baseline.

EPCA expressly bars NHTSA from considering the fuel economy of electric vehicles and dual-fueled vehicles, such as PHEVs, in setting fuel-economy standards for passenger cars.⁵ Congress included this explicit prohibition to ensure that electric vehicles remain the compliance flexibility that Congress intended them to be—and do not become a BEV mandate.

NHTSA ignores EPCA’s clear statutory prohibition by interpreting 49 USC § 32902(h) as preventing NHTSA from setting CAFE standards that require application of dedicated alternative fueled vehicles during the only the standard setting years. NHTSA admits that it modeled “the application of BEV technology in MYs outside the standard-setting years . . . to account for BEVs that manufacturers may produce for reasons other than the CAFE standards.”⁶ Despite the clear prohibition, NHTSA openly considered electric vehicles—including those currently in the fleet and EVs the agency predicted would be produced in response to California’s and other States’ Advanced Clean Car II (ACC II) mandates and EPA’s prior greenhouse-gas standards— in deciding the maximum fuel-economy level that automakers can feasibly achieve.⁷ See Appendix A - AFPM Legal Review of NHTSA’s Proposed CAFE Standards for MYs 2027-2032 Passenger Cars and Light Trucks and Fuel Efficiency Standards for MYs 2030-2035 Heavy-Duty Pickup Trucks and Vans (referred to herein as “AFPM Comments” appended here as Attachment A) at pp 15-25 and Review of the NHTSA’s CAFE Model in Analyzing The Proposed CAFÉ Standards for MYs 2027-2032 Passenger Cars and Light Trucks and Fuel Efficiency Standards (referred to as the “Trinity Report” appended as Attachment B) at pp. 2-7. NHTSA also included in its baseline for passenger cars and light-duty trucks projected ZEV penetration rates pursuant to California’s ACC II rulemaking in both the baseline and standard setting years. NHTSA cannot rely on ACC II in the development of its baseline

⁵ Footnote 4: 49 U.S.C. § 32902(h)(1) (in “carrying out” the responsibility to set fuel-economy standards, NHTSA “may not consider” the fuel economy of electric vehicles) and 32902(h)(2) (NHTSA shall consider dual-fueled vehicles, such as PHEVs “to be operated only on gasoline or diesel fuel.”).

⁶ Footnote 5: Id., DEIS at 2-14 to 2-15, and Technical Support Document for the Corporate Average Fuel Economy Standards for Passenger Cars and Light Trucks for Model Years 2027–2032 and Fuel Efficiency Standards for Heavy-Duty Pickup Trucks and Vans for Model Years 2030–2035 at 3-65 to 3-84.

⁷ Footnote 6: “NHTSA has not taken the additional step of removing BEVs from the baseline fleet, and we continue to assume that manufacturers will meet their California ZEV obligations whether or not NHTSA sets new CAFE standards. We reflect those manufacturer efforts in the baseline fleet.” 88 Fed. Reg. 56,319.

or proposed standards because (1) ACC I and ACC II are expressly preempted by the Clean Air Act (CAA), and (2) EPA has not determined whether it will grant a waiver for ACC II. See AFPM Comments (Attachment A) at pp. 63-65 and Trinity Report at 7-11 for a complete discussion regarding the impact of NHTSA’s illegally considering ACC II’s EV mandates in the CAFE baseline. Finally, NHTSA also included in the model the fuel economy of additional electric vehicles that manufacturers would introduce, irrespective of the CAFE standard, during the standard setting years MY2027-2032. See AFPM Comments (Attachment A) at pp.15-25 for a complete discussion regarding NHTSA’s illegal CAFE baseline. Certainly, alternatives that violate the law cannot be “reasonable.”

Response

NHTSA disagrees that the modeled No-Action Alternative does not comport with all relevant statutory and other authorities. For additional discussion of the factors that NHTSA considered when developing the No-Action Alternative, please see Section IV of the final rule preamble.

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

In projecting the baseline fleet—the step taken before NHTSA begins to analyze the “maximum feasible” factors in Section 32902(f)—NHTSA analyzes what manufacturers’ passenger car and light truck fleets would look like absent additional regulatory action by NHTSA. 88 Fed. Reg. at 56,319; see 50 Fed. Reg. 40,528, 40,533-34 (Oct. 4, 1985) (stating that, when setting fuel economy standards, NHTSA has consistently projected what the fleet would likely look like if NHTSA made no change and then “considered what, if any, additional actions the manufacturers could take to improve their fuel economy”). The “baseline should be the best assessment of the way the world would look absent regulatory action.” Off. of Mgmt. & Budget, Circular A-4 at 15 (2003). “[T]his ensures that [NHTSA’s] analysis can appropriately capture manufacturer decision making about their vehicle fleets for reasons other than CAFE standards (e.g., other regulatory programs and manufacturing decisions).” 88 Fed. Reg. at 56,156.

In the Proposal, NHTSA appropriately projects the baseline fleet as “consist[ing] of every vehicle model in MY 2022 in mostly every configuration that has a different compliance fuel economy value. . . .” 88 Fed. Reg. at 56,164; see also 49 U.S.C. § 32904(a)(2) (providing for a petroleum-equivalent fuel economy value for electric vehicles to be included in the calculation of a manufacturer’s average fuel economy). This projection thus accounts for the growing market penetration of electric vehicles, which manufacturers are already producing in response to market demand, their own strategic decisions, and other legal obligations.

Not only is NHTSA’s modeling of the No-Action alternative consistent with Section 32902(h); in fact, long-standing principles of reasoned decisionmaking would forbid NHTSA from ignoring the existence of BEVs in the nation’s light-duty fleet and their dramatic year-over-year increases in sales. E.g., NRDC v. Herrington, 768 F.2d 1355, 1408 (D.C. Cir. 1985) (stating “it would be patently unreasonable” for agency to refuse to recognize “dramatic[.]” changes in regulated industry). Indeed, the use of a national baseline fleet with no BEVs would require “a massively counterfactual assumption” of the kind courts find “[p]articularly troubling” as a basis for agency action. Sokol v. Kennedy, 210 F.3d 876, 881 n.11 (8th Cir. 2000); see also Animal Legal Def. Fund, Inc. v. Perdue, 872 F.3d 602, 619 (D.C. Cir. 2017) (“Reliance on

facts that an agency knows are false at the time it relies on them is the essence of arbitrary and capricious decisionmaking.”) (cleaned up); *Appalachian Power Co. v. EPA*, 249 F.3d 1032, 1053 (D.C. Cir. 2001) (“While courts routinely defer to agency modeling of complex phenomena, model assumptions must have a rational relationship to the real world.” (cleaned up)); cf. *Ctr. for Auto Safety v. Peck*, 751 F.2d 1336, 1365 (D.C. Cir. 1985) (upholding agency’s rejection of “the most unlikely set of extreme assumptions” that were “virtually impossible . . . to occur in the real world”). As the D.C. Circuit stated almost forty years ago, it would be “wholly futile for [courts] to require [an agency] to conform its decisionmaking procedures to the statute, but permit it to trudge through the correct procedure based on information that is now incontestably antique.” *Herrington*, 768 F.2d at 1408.

Just as NHTSA cannot ignore the growing presence of BEVs in the real world, it also cannot assume that regulated parties—here, automakers—will fail to comply with their legal obligations. Courts routinely uphold agencies’ inclusion of such compliance in their baselines for regulatory analyses.⁸ Moreover, agencies, like courts, should honor the longstanding “presumption that parties act lawfully.” See *Schwab v. Reilly*, 560 U.S. 770, 790 (2010) (citing *United States v. Budd*, 144 U.S. 154, 163 (1892)). Doing otherwise, particularly in the face of evidence indicating compliance is the norm, would be arbitrary and capricious. *Motor Vehicle Mfrs. Ass’n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43 (1983) (agency may not “offer[] an explanation for its decision that runs counter to the evidence”). Given the facts on the ground and principles of reasoned decisionmaking, NHTSA correctly chose to model BEV growth in its No-Action baseline both because this growth plainly exists in the real-world fleet today and because NHTSA can and should assume automakers will comply with their legal obligations regardless of any action NHTSA may take in its rulemaking.

Given NHTSA’s duty to project a No-Action baseline that accounts for sharply growing zero- emission vehicle sales, modeling compliance with California’s Advanced Clean Cars I (“ACCI”), Advanced Clean Cars II (“ACCI”), and Advanced Clean Trucks (“ACT”) regulations is a reasonable methodology to do so, at least in the event that California is granted its requested waiver for ACCI and ACCII thus becomes enforceable. There is no shortage of projections of electric vehicle sales in the regulated model years from industry analysts,⁹ and automaker commitments imply penetration well above NHTSA’s No-Action alternative.¹⁰ However, using state zero-emission vehicle standards to model the progress of electric vehicle sales offers advantages in precision, transparency, and consistency. NHTSA’s methodology is more precise and transparent than one based on industry analysis or commitments because it models progress toward definite targets codified by States in state regulations, rather than choosing between industry forecasts that offer differing estimates based on proprietary analyses. Likewise, automakers’

⁸ Footnote 193: E.g., *NRDC v. Thomas*, 838 F.2d 1224, 1238 (D.C. Cir. 1988) (holding, in part, that using “[State- Implementation-Plan]-required emissions rates as the baseline” was “a quite reasonable interpretation” of relevant provision of Clean Air Act); *Cooling Water Intake Structure Coal. v. EPA*, 905 F.3d 49, 81 (2d Cir. 2018) (quoting “environmental baseline” requirements for Endangered Species Act consultations as including “the past and present impacts of all Federal, State, or private actions” and distinguishing those from impacts resulting from agencies exercising discretion); *Am. Rivers v. FERC*, 201 F.3d 1186, 1192 (9th Cir. 1999) (upholding agency use of facility’s operations pursuant to terms and conditions of existing license as no action baseline).

⁹ Footnote 208: See, e.g., n.198 & 199, supra.

¹⁰ Footnote 209: Compare U.S. EPA, Proposed Emission Standards, MY2027-32, 88 Fed. Reg. at 29,192 (Table 1) (tabulating a total 48.6% combined light-duty market share for BEVs and PHEVs by 2030 implied by automaker announcements) with 88 Fed. Reg. at 56,278-79 (Tables IV-8, IV-10) (projecting total light- duty BEV penetration rate of 27.7% and PHEV penetration rate of 0.8% by 2030 in No-Action alternative).

historical compliance with state zero-emission vehicle standards is a superior basis for NHTSA’s projection than automakers’ non-binding and dynamic public statements. Finally, continuing to use state zero-emission vehicle standards to project electric vehicle sales is consistent with NHTSA’s methodology in the MY2024-26 amendments, promoting a straightforward comparison between the two actions.

As the California Air Resources Board explains in the attached report, NHTSA’s No-Action fleet appears to overestimate the sales of zero-emission vehicles necessary to comply with ACCI and ACCII. See Attachment 1, California Air Resources Board Technical Analysis of the National Highway Traffic Safety Administration’s Proposed 2027-2032 Model Year Light-Duty Fuel Economy Standards. Even so, NHTSA’s methodology is likely to prove a highly conservative one for estimating zero-emission vehicle adoption in the No-Action scenario. Most critically, NHTSA models ACCI/II and ACT compliance only in the States that have adopted or will likely adopt those regulations; but the data is clear that electric vehicle sales are increasing in States that have not adopted and are unlikely to adopt any of these regulations. For example, in 2022, the second and third leading States for new electric vehicle registrations were Texas and Florida (which have not adopted ACCI/II or ACT), with their combined 2022 registrations reaching almost 367,000, well over a third of California’s 2022 registrations.¹¹ Because NHTSA’s modeling does not account for significant zero-emission vehicle sales outside of the States adopting ACCI/II and ACT, its No-Action scenario likely significantly underestimates the zero-emission vehicles in the baseline fleet. Because this underestimation may result in less stringent standards than are truly the “maximum feasible” standards, 49 U.S.C. § 32902(a), NHTSA should consider modeling zero-emission vehicle adoption in States not adopting ACCI/II and ACT.¹²

Response

NHTSA agrees that the modeled No-Action Alternative comports with all relevant statutory and other authorities. For additional discussion of the factors that NHTSA considered when developing the No-Action Alternative, please see Section IV of the final rule preamble. NHTSA also considered the States and Cities Joint Comment, among other public comments on the No-Action Alternative, to modify modeling of how manufacturers have indicated their intent to deploy electric vehicles (EVs) consistent with what would be required under Advanced Clean Cars II, regardless of whether it becomes a binding legal obligation, for the final rule. Please see final rule preamble Section III.C.5 and Final TSD Chapter 2.5 for additional discussion of how NHTSA updated its modeling for the final rule.

B.1.2 Reasonable Range of Alternatives

Comment

Comment Number: NHTSA-2022-0075-0032

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

I. THE DEIS FAILS TO EVALUATE REASONABLE ALTERNATIVES.

Regulations implementing NEPA require NHTSA to evaluate “reasonable alternatives” to the proposed action.¹³ “An alternative is ‘reasonable’ if it is ‘technically and economically practical or feasible and

¹¹ Footnote 210: e Fuels Data Center, Electric Vehicle Registrations by State, *supra* note 194.

¹² Footnote 211: One reasonable and available method for projecting these sales might be the most recent historical growth rate of electric vehicle sales in these States in the prior model year(s) for which data is available.

¹³ Footnote 2: 40 CFR 1502.14(s).

meet[s] the purpose and need of the proposed action.”¹⁴ First, none of the alternatives are reasonable because they violate EPCA, as amended by EISA, 49 U.S.C. §§ 32901-32919, and two of the proposed alternatives cannot be implemented. Moreover, none of the proposed alternatives analyze the maximum feasible standards that can be achieved by passenger and light-duty internal combustion engine vehicles (ICEVs).

B. Two of the proposed alternatives for CAFE cannot be implemented within the standard setting years.

The TSD and DEIS evaluate four CAFE alternatives (see Table 1-3 from the DEIS).¹⁵

[See original attachment for Table 1-3: Regulatory Alternatives Under Consideration for Mys 2027-2032 Passenger Cars and Light Trucks]

As detailed extensively in AFPM’s comments, and as expressed by original equipment manufacturers (OEMs),¹⁶ the preferred alternatives cannot be implemented during the standard setting years because:

- CAFE compliance data demonstrates that OEMs are unable to comply with less stringent existing standards, let alone more stringent increases.¹⁷
- AFPM and OEMs express grave concern that the inadequate supply of critical minerals (lithium, cobalt, nickel, copper, and rare earths) needed to produce batteries for EVs, PHEVs, and other hybrid vehicles prevent compliance with the preferred alternative during the standard setting years.¹⁸
- Current and planned battery and EV production rates are insufficient to support the EV adoption rates contemplated by the proposed standards.¹⁹
- The lack of domestic and global supplies of critical minerals and metals required to expand the electricity grid and construct national charging infrastructure within the timeline of the proposed standards renders the proposed standards technically infeasible.
- Electricity generation capacity and the electrical transmission and distribution grid cannot be expanded during the proposal’s period to support the EV penetration rates necessitated by all alternatives other than the “no action” alternative.
- Reliable, equitable, and affordable charging infrastructure needed to power EVs mandated by the preferred alternative will not be deployed nationally within the proposed rule’s time period.

¹⁴ Footnote 3: *Ctr. for Biological Diversity & Sierra Club v. Fed. Energy Regulatory Comm'n*, 67 F.4th 1176 (D.C. Cir. 2023) (citing 43 CFR § 46.420(b)).

¹⁵ Footnote 7: TSD at 1-24. See also DEIS at 2-4 to 2-10.

¹⁶ Footnote 8: See Alliance for Automotive Innovation, Comments to the Environmental Protection Agency, Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles, Proposed Rule, Docket No. EPA-HQ-OAR-2022-0829 (hereinafter AAI Comments) at 1-60, and 66-70.

¹⁷ Footnote 9: AFPM Comments at 26-43 and 72-77.

¹⁸ Footnote 10: *Id.* at 25-40; AAI Comments at 14-24.

¹⁹ Footnote 11: AFPM Comments at 37-38; AAI Comments at i-ii, and 44-46.

NHTSA’s modeled fleet-wide achieved CAFE by manufacturer (reproduced Figure 8-4 below) confirms that few manufacturers (and mostly luxury EV producers) could achieve the standards set forth in Alternative PC3LT5 and PC6LT8 —these alternatives are thus prima facie unreasonable.²⁰

[See original attachment for Figure 8-4: Modeled Fleet-wide Achieved CAFÉ by Manufacturer]

Therefore, NHTSA failed to evaluate reasonable alternatives as required by 40 CFR § 1502.14(a).

C. None of the alternatives analyze the maximum feasible standards that can be achieved by ICEVs.

Although EPCA clearly directs NHTSA not to consider the fuel economy of any electric vehicle, from any model year, for any purpose when setting fuel-economy standards, NHTSA failed to include any alternative that could be achieved by ICEVs. For example, Research Octane Number (RON) and octane sensitivity improve engine performance, reduce fuel consumption, and lower greenhouse gas emissions.²¹ While NHTSA need not consider every alternative, and given that NHTSA is currently litigating in the Court of Appeals for the D.C. Circuit the propriety of its practice of considering EVs in setting CAFE standards, the Agency must consider alternatives that can be achieved by ICEVs and does not force electrification of the fleet.

Response

NHTSA disagrees that the Proposed Action and alternatives fail to meet the purpose and need of EPCA, as amended by EISA, and NEPA and its implementing regulations. Additional discussion of the alternatives that NHTSA considered in the final rule is provided in Section IV of the final rule preamble, and NHTSA’s conclusions that the Preferred Alternative is maximum feasible are provided in Section VI of the final rule preamble.

B.1.3 Suggestions for the Preferred Alternative and Other Alternatives to Consider

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

NHTSA tentatively concluded that the Preferred Alternative standards are the “maximum feasible,” 88 Fed. Reg. at 56,133, and we agree that those standards are technologically feasible, economically practicable, and conserve energy compared to the No- Action Alternative. However, we urge NHTSA to consider whether more stringent standards— including the PC3LT5 Alternative and a more stringent hybrid alternative, such as PC2.5LT7²²— are ultimately the “maximum feasible.”

²⁰ Footnote 12: Preliminary Regulatory Impact Analysis (PRIA), July 2023 Figure 8-4 at 8-6.

²¹ Footnote 13: High RON gasoline and alcohol fuels have been proven to reduce fuel consumption and net CO2 emissions. R. Speth, E. Chow, R. Malina, S. Barrett, J. Heywood, and W. Green, Economic and Environmental Benefits of Higher-Octane Gasoline, Environ. Sci. Technol. 2014, 48, 12, 6561–6568.

²² Footnote 3: This is an example of a hybrid alternative rather than a specific stringency level for which we are advocating.

NHTSA is required to set “maximum feasible” fuel economy standards separately for passenger cars and light trucks, “which gives NHTSA discretion, by law, to set CAFE standards that increase at different rates for cars and trucks.” *Id.* at 56,133 n.9. The record clearly demonstrates that more stringent standards than the Preferred Alternative may be “maximum feasible” for light trucks.

Thus, we urge NHTSA to consider whether more stringent standards than the Preferred Alternative—including PC3LT5 and possible hybrid alternatives such as PC2.5LT7—are ultimately the “maximum feasible” based on the full record before the agency.

Response

NHTSA discusses alternatives proposed by commenters in Section IV of the final rule preamble. Please see that section for a discussion of comments and alternatives considered in this final rule. Please also refer to Section VI of the final rule preamble for a discussion of why NHTSA considers the Preferred Alternative to be maximum feasible.

B.1.4 Resource Areas Dismissed from Further Consideration

Comment

Comment Number: NHTSA-2022-0075-0030

Commenter: Roselie Bright

Please obtain an environmental epidemiologist to update the review of recent literature and extract important inputs into the public health effects model. Doing so might clear up some of my confusion for a few specific points:

a. The effects of noise were dismissed because in some traffic situations, electric vehicles need to make artificial noise to alert pedestrians, even though overall, combustion engine vehicles are still much louder than electric vehicles. It is clear to me that as the combustion engine vehicles are replaced by electric vehicles, the overall noise produced by the fleet of vehicles will decrease. Where epidemiology comes into play is the fact that the most alarming studies of noise pollution are recent. At real-world traffic noise levels, they document the following adverse health impacts: increased blood pressure, heart disease, raised stress hormones, brain damage, cancer, and death [1-45].

Response

NHTSA has updated Section 2.4, *Resource Areas Dismissed from Further Consideration in this EIS and EIS Organization*, to clarify the discussion of reasons why noise was dismissed from further consideration. NHTSA is not dismissing that traffic noise generally has health impacts; rather, NHTSA believes that the analysis in EISs since 2010 through this EIS (and in accompanying rulemaking documents) show that there is no significant impact from the action of setting CAFE and FE standards; therefore, more study of the potential noise impacts of setting CAFE and FE standards is not warranted, which is the relevant standard under NEPA. Section 2.4 contains a brief assessment of the noise impacts of setting CAFE and fuel efficiency standards, in proportion to their significance, in accordance with 40 Code of Federal Regulations (CFR) 1502.2(b).

NHTSA measures one component of noise impacts of the Proposed Action and alternatives in its modeling, which is the social cost of increased noise due to additional vehicle miles traveled (VMT) from the rebound effect. The values employed in the model are discussed in Chapter 6.2.3 of the TSD and the

results of the analysis are presented in Chapter 8.2.4.3 of the Final Regulatory Impact Analysis (FRIA). However, both the underlying research and results of NHTSA’s analysis show that the resulting impacts are extremely small. There is also uncertainty, discussed further in Section 2.4, *Resource Areas Dismissed from Further Consideration in this EIS and EIS Organization*, around how manufacturers will respond to CAFE and FE standards with different vehicle technologies (e.g., hybrid and EVs), which could produce additional noise benefits. NHTSA will continue to follow research in this area and update future modeling and analysis as necessary.

B.2 Energy

B.2.1 Affected Environment

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

Increased fuel efficiency will reduce fuel consumption and may reduce the amount of oil that is produced and refined within the United States. Both reductions will result in reduced GHG emissions. 88 Fed. Reg. at 56,317. These anticipated GHG emissions reductions are necessary to help stave off the worst effects of a climate crisis that is primarily caused by anthropogenic GHG emissions.²³ which is already afflicting our States and Cities.

Response

NHTSA agrees that increased fuel efficiency will decrease fuel consumption by the vehicles manufactured in the model years covered by the standards and as those vehicles replace older vehicles in the fleet. NHTSA includes further discussion of the standards’ impact on fuel production and refining in Section III.G.2(b)(3) of the final rule preamble. The Final EIS also includes a discussion of each fuel types’ greenhouse gas (GHG) emissions and includes a brief discussion of the impact of predicted decreases in overall fuel consumption on GHG emissions in the future in Section 3.1, *Introduction*.

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

Our States and Cities also recognize that reduction in fuel use can benefit our national security. Experts have noted numerous foreign policy costs that arise from the domestic consumption of foreign oil, including: (1) disruptions in oil supply; (2) political realignment from dependence on imported oil that limits United States alliances and partnerships; (3) increasing the power of oil- exporting countries to enact policies that are contrary to United States interests; and (4) the maintenance of United States military presence in the Middle East arising from interest in protecting oil interests.²⁴ Reducing

²³ Footnote 22: See INTERGOVERNMENTAL PANEL ON CLIMATE CHANGE, CLIMATE CHANGE 2021: THE PHYSICAL SCIENCE BASIS, SUMMARY FOR POLICYMAKERS 4 (2021), https://www.ipcc.ch/report/ar6/wg1/downloads/report/IPCC_AR6_WGI_SPM.pdf [hereinafter “IPCC 2021 Summary for Policymakers”].

²⁴ Footnote 16: 88 Fed. Reg. at 56,318 (citing COUNCIL ON FOREIGN RELATIONS, NATIONAL SECURITY CONSEQUENCES OF U.S. OIL DEPENDENCY (Oct. 2006), https://cdn.cfr.org/sites/default/files/report_pdf/0876093659.pdf).

dependence on imported oil could “lower U.S. military and foreign policy costs of safeguarding the U.S. oil supply and reduce revenue to regimes that are considered inimical to U.S. interests.”²⁵

Second, decreasing domestic demand for petroleum could reduce consumers’ exposure to oil price shocks. 88 Fed. Reg. at 56,318. Since the 1970s, Americans have experienced five significant gas price shocks following spikes in the world oil market.²⁶ Oil price shocks have been a contributing factor to economic recessions.²⁷ And with climate change, an increased frequency of extreme weather events that disrupt foreign and domestic energy supplies can be expected, causing supply shortages and price spikes.²⁸ For example, Hurricane Ida caused a temporary disruption of nine-tenths of crude oil production in the Gulf of Mexico, resulting in Gulf Coast gasoline prices rising by 49% over the same time the previous year.²⁹

Decreasing the dependency of the United States on global oil markets helps insulate consumers from such global price shocks and supply disruptions. Even though the United States has positive net oil exports, the United States is not self-sufficient in petroleum production, and consumers still feel the effects of price shocks as the price of oil is determined by the global markets. See 88 Fed. Reg. at 56,317, 56,328. For example, average gas prices in the United States reached record highs in 2022 after Russia invaded Ukraine, which threatened global oil supply and increased crude oil prices.³⁰ Thus, “regardless of whether exports equal or even exceed imports, global supply shocks will still impose costs” on U.S. consumers, among others.³¹ Stricter fuel economy standards and lower fuel consumption can help insulate the United States from these effects. Moreover, more stringent fuel economy standards could further help stabilize oil costs by helping to mitigate climate change (discussed in more depth below), which will reduce the frequency and intensity of extreme weather events that disrupt oil production.

Accordingly, our States and Cities support improving fuel economy, as it provides multiple benefits to consumers.

Response

NHTSA agrees that improving fuel economy provides multiple benefits to consumers. Final EIS Chapter 3, *Energy*, describes the fuel use and environmental impacts of each alternative. Readers may consult Chapters 4, 5, and 7 of the FRIA and Chapter 6 of the TSD, which are incorporated in this Final EIS by reference, for a more extensive description of economic and energy security impacts of this action.

B.2.1.1 Gasoline

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

Gasoline used to power light-duty vehicles accounted for around 41% of total petroleum consumption in the United States in 2022.³² Due to fossil fuel combustion, the transportation sector generates the largest share of total greenhouse gas (“GHG”) emissions in the United States.³³ Light-duty trucks and passenger cars account for 37.1% and 20.7% of transportation sector emissions in the United States, respectively, and approximately 16.5% of total GHG emissions in the United States.³⁴ Moreover, the extraction, transport, and refining of crude oil is a significant source of GHG emissions, constituting about 5% of total global GHG emissions.³⁵

Historically, NHTSA has considered the national balance of payments in evaluating the need to conserve energy, “because of concerns that importing large amounts of oil created a significant wealth transfer to oil-exporting countries and left the U.S. economically vulnerable.” 88 Fed. Reg. at 56,316-17 (citing 42 Fed. Reg 63,184, 63,192 (Dec. 15, 1977)).

In the Proposal, NHTSA recognizes that, even as a net exporter of petroleum products,³⁶ the U.S. continues to rely on oil imports and that reducing vulnerability to oil price shocks remains important. Id. NHTSA could strengthen its analysis by acknowledging that the U.S. consumed more petroleum than it produced in 2022, and that the U.S. remained a net crude oil importer in 2022, importing about 6.28 million barrels per day of crude oil and exporting about 3.58 million barrels per day.³⁷ NHTSA acknowledges that, “[i]n 2021, the transportation sector accounted for 78.8 percent of total U.S. petroleum consumption,” Draft Environmental Impact Statement (“DEIS”) at S-8, and that

³⁶ Footnote 180: In 2022, total petroleum exports were about 9.58 million barrels per day and total petroleum imports were about 8.32 million barrels per day. U.S. Energy Information Administration, Oil and Petroleum Products Explained: Oil Imports and Exports (Oct. 2, 2023), <https://www.eia.gov/energyexplained/oil-and-petroleum-products/imports-and-exports.php>. The EIA projects that the U.S. will remain a net exporter of petroleum products through 2050. U.S. Energy Information Administration, Annual Energy Outlook AEO2023 (Mar. 2023), at 23, https://www.eia.gov/outlooks/aeo/pdf/AEO2023_Narrative.pdf; see also U.S. Energy Information Administration, Annual Energy Outlook 2022 with Projections to 2050 (Mar. 2022), at 32, https://www.eia.gov/outlooks/aeo/pdf/AEO2022_Narrative.pdf.

³⁷ Footnote 181: U.S. Energy Information Administration, Oil and Petroleum Products Explained: Oil Imports and Exports (Oct. 2, 2023), <https://www.eia.gov/energyexplained/oil-and-petroleum-products/imports-and-exports.php>.

“transportation demand is expected to continue to increase,” 88 Fed. Reg. at 56,316. The proposal “aims to improve fleet-wide fuel efficiency and to help reduce the amount of petroleum consumed in the U.S,” *id.*, which will reduce expenditures on foreign oil and protect consumers from global oil price shocks.

Response

The Final EIS includes appropriate descriptions of the greenhouse gas (GHG) emissions generated by the transportation sector during production of each light-duty (LD) and HDPUV fuel type. In particular, Section 3.2.1, *Gasoline*, describes the GHG emissions released during the crude oil extraction, transportation, and refinement of crude oil.

The Final EIS discusses the status of the United States as a net importer and the environmental implications of reducing net petroleum imports in the United States in Section 3.2.1.4, *Petroleum Imports*. Readers may consult Sections III and VI of the final rule preamble, Chapters 4, 5, and 7 of the FRIA, and Chapter 6 of the TSD, which are incorporated in this Final EIS by reference, for a more extensive description of economic and energy security impacts of this action.

B.2.1.2 Diesel and Biofuels

Comment

Comment Number: NHTSA-2022-0075-0032

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

IV. THE DEIS DOES NOT ADEQUATELY ADDRESS THE CONFLICTS BETWEEN THE PROPOSED STANDARDS AND OTHER FEDERAL POLICIES.

The DEIS violates 40 CFR § 1502.16(a)(5) by ignoring how the proposed EV mandate conflicts with other federal programs. The proposed standards, and by extension, the DEIS, stands in direct contrast to other legislation, such as the Renewable Fuel Standard Program (RFS), whereby Congress mandated that “gasoline sold or introduced into commerce in the United States” must contain renewable fuels³⁸ and, in 2023 (and beyond), must include billions of gallons of renewable fuel.³⁹ Congress created the RFS, which requires increasing volumes of renewable fuel to be blended into transportation fuel. The four categories of renewable fuel must emit anywhere from 20 percent to 80 percent fewer GHGs relative to the fossil fuel it replaces. While the DEIS addresses ethanol and biodiesel, it lacks any discussion of renewable diesel, which can achieve up to 80% GHG emissions reductions, as well as higher-octane fuels. EPA's RFS data show that the U.S. market reached 3.6 billion gallons of biomass-based diesel in 2022.⁴⁰

In response to this mandate, U.S. refineries dramatically increased renewable fuel production and invested billions of dollars to expand U.S. production of liquid renewable fuels, which can now achieve

³⁸ Footnote 34: 42 U.S.C. § 7545(o)(2)(A)(i).

³⁹ Footnote 35: *Id.*, § 7545(o)(2)(B); 87 Fed. Reg. 39,600 (July 1, 2022).

⁴⁰ Footnote 36: Spreadsheet of RIN Generation and Renewable Fuel Volume Production by Fuel Type for the Renewable Fuel Standard for December 2022. Retrieved from <https://www.epa.gov/fuels-registration-reporting-and-compliance-help/spreadsheet-rin-generation-and-renewable-fuel-0>.

up to an 86 percent GHG emissions reduction compared to petroleum fuels.⁴¹ One of which is renewable diesel that is a “drop-in” fuel and can be used in the existing diesel fuel distribution system and existing diesel vehicles.

According to the Energy Information Agency’s June 2023 Short-Term Energy Outlook (STEO), biomass-based diesel (which includes biodiesel and renewable diesel) production averaged 3.1 billion gallons in 2022, and EIA expects production to average 4.0 billion gallons in 2023 and 4.8 billion gallons in 2024. EIA expects ethanol and renewable oxygenate production to increase from 18.4 billion gallons in 2022 to 19.2 billion gallons in 2023, and to 20.4 billion gallons in 2024.

[See original attachment for chart of existing and expected U.S. renewable diesel production capacity (2010-2023)]

Figure 1. Existing and Expected US Renewable diesel production capacity (2010- 2024).⁴²

In response to the RFS and other government programs encouraging the production of lower carbon renewable liquid fuels, U.S. refiners are undertaking significant capital expenditures to lower the carbon intensity of fuel such as taking advantage of Congress’ 45Q tax credit for carbon capture and sequestration (CCS). Ethanol producers are also looking to use CCS to reduce carbon intensity from the 15 billion gallons of ethanol blended into our nation’s gasoline.⁴³ Similarly, renewable diesel and sustainable aviation fuel production capacity will total 5.1 billion gallons per year if all announced expansion projects, which represent \$10.8 billion in investments, are completed.⁴⁴ Yet despite the rapid growth in renewable diesel production mandated by Congress, the DEIS fails to account for this program and the environmental benefits it brings.

Response

The Final EIS includes Section 3.2.3.4, *Renewable Diesel*, which describes LD and HDPUV renewable diesel use as well as the environmental benefits and impacts of renewable diesel. NHTSA believes this discussion appropriately reflects the Council on Environmental Quality (CEQ)’s instruction to discuss impacts in proportion to their significance. 40 CFR 1502.2(b). As described in Section 3.1, *Introduction*, the CAFE Compliance and Effects Model (CAFE Model) shows that diesel consumption constitutes an extremely small portion of LD vehicle fuel use in 2022 and is expected to be an even smaller portion of fuel use in 2050. While diesel consumption makes up a larger share of HDPUV energy consumption in 2022, not only is the HDPUV fleet a fraction of the size of the LD fleet, but the share of diesel consumption as a percentage of total energy consumption in the HDPUV fleet is also expected to decline by 2050. Additional discussion of NHTSA’s consideration of alternative fuels is discussed in Section III.B of the final rule preamble.

B.2.2 Environmental Consequences

Comment

Comment Number: NHTSA-2022-0075-0032

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

Ignoring activities and their related environmental impacts to transition the entire transportation fleet. In the context of this rulemaking, where ICEVs emit much of their carbon from the tailpipe and EVs emit them mostly during the vehicle production and recharging phases, lifecycle analyses of each technology are critically important and the only way of ensuring an apples-to-apples comparison. While Chapter 6 details NHTSA's lifecycle assessment for building materials, the DEIS neglects to discuss environmental impacts associated activities required to build out the electricity grid and charging stations necessitated by this rulemaking, which is contrary to NEPA.

Response

NHTSA agrees that there will be environmental impacts related to meeting the increased energy demand associated with the fleet transitioning away from internal combustion engine (ICE) vehicles toward alternative methods of vehicle propulsion. NHTSA discusses the environmental impacts of increasing energy resources, including coal mining, natural gas production, and renewable energy production in Section 3.2.2, *Electricity*. NHTSA has expanded Section 3.2.2, *Electricity*, to include the environmental impacts of vehicle recharging station development. Section 3.2.1, *Gasoline*, which includes Sections 3.2.1.1, *Petroleum Extraction*, 3.2.1.2 *Petroleum Transportation*, 3.2.1.3 *Petroleum Refining*, 3.2.1.4, *Petroleum Imports*, and 3.2.1.5, *Fuel Transportation, Storage, and Distribution*, details the analogous environmental impacts related to gasoline. Similarly, Sections 3.2.3, *Diesel and Biofuels*, and 3.2.4, *Natural Gas*, detail the analogous environmental impacts of other types of ICE vehicles. NHTSA agrees that being able to look at these impacts as an apples-to-apples comparison is useful for the decision-maker and stakeholders.

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

All four of the alternatives proposed by NHTSA would have a long-term positive effect on consumers. NHTSA projects that under the Preferred Alternative, fuel savings will exceed the technology costs necessary to comply with the standards. 88 Fed. Reg. at 56,138. Specifically, NHTSA estimates that the Preferred Alternative could reduce the lifetime fuel costs of passenger cars by \$302 and a light truck by \$1,389, while increasing the average costs, respectively, by \$654 and \$1,064. Preliminary Regulatory Impact Analysis ("PRIA") at 8-23, Table 8-3; 88 Fed. Reg. at 56,138; see also id. at 56,139, Table I-6. And drivers will not only experience lower costs as a result of new vehicles' decreased fuel consumption, but also will benefit from "increased mobility that results from a lower cost of driving their vehicle . . . and fewer refueling events." 88 Fed. Reg. at 56,285.⁴⁵

⁴⁵ Footnote 4: See also NHTSA, Preliminary Regulatory Impact Analysis: Corporate Average Fuel Economy Standards for Passenger Cars and Light Trucks for Model Years at 2027 and Beyond and Fuel Efficiency Standards for Heavy-Duty Pickup Trucks and Vans for Model Years 2030 and Beyond at 8-40 (July 2023).

Moreover, these proposed improvements in fuel economy benefit consumer welfare beyond reduced fuel expenditures for those buying new vehicles. Gasoline consumption in the United States is expected to decrease as vehicle manufacturers produce more fuel-efficient vehicles in response to the more stringent standards. 88 Fed. Reg. at 56,253. Indeed, lower total fuel consumption is expected even if total miles driven increase slightly. See *id.* at 56,288, Table IV-22. NHTSA estimates that the Preferred Alternative would “reduce fuel consumption by 88 billion gallons through [calendar year] 2050.” *Id.* at 56,328. Decreasing the domestic consumption in the United States will in turn produce “a corresponding decrease in the Nation’s demand for crude petroleum, a commodity that is traded actively in a worldwide market.” *Id.* at 56,253. Because the United States accounts for a significant share of global oil consumption, its decreasing demand will “exert some downward pressure on worldwide prices,” thus tending to lower gas prices for all consumers. *Id.*⁴⁶ This decrease in domestic demand for oil will have some important externalities that positively affect consumers directly and our States and Cities more generally.

Response

This Final EIS describes the fuel use and environmental impacts of each alternative. Readers may also consult Chapter 6 of the TSD and Chapter 8 of the FRIA, which are incorporated in this EIS by reference, for a more extensive description of the methodology that NHTSA used to model the economic and energy security impacts of this action and for a discussion of other consumer costs and benefits.

B.2.2.1 Cumulative Impacts

Comment

Comment Number: NHTSA-2022-0075-0030

Commenter: Roselie Bright

4. The CAFE model assumed that for electricity generation, the majority of sources would continue to be fossil fuel [Section 3.2.2].

- Please include in your analysis the impact of expanding home EV battery charging from home solar panels.

Response

NHTSA has expanded Section 3.2.2.1, *Electricity*, to include information about the potential growth of residential rooftop photovoltaic panels. The United States added 6.4 gigawatts of small-scale solar or rooftop solar capacity in 2022, the most in a single year (EIA 2023w). If the increase in residential solar continues, it may lead to a decrease in upstream emissions from charging EVs.

In addition, for the analysis supporting the final rule, NHTSA mapped National Renewable Energy Laboratory (NREL) 2022 Standard Scenarios projections for electricity generation into Greenhouse Gases, Regulated Emissions, and Energy Use in Technologies (GREET) 2023 to develop the electricity emissions factors for the CAFE Model. To the extent that the NREL projections assume a decreasing share of fossil fuel for electricity generation, that is now incorporated in our analysis. Additional discussion of how NHTSA incorporated these estimates and the resulting impacts is provided in Chapter

⁴⁶ Footnote 5: See also U.S. Energy Info. Admin., Oil and petroleum products explained: Use of oil (last updated Aug. 22, 2023), <https://www.eia.gov/energyexplained/oil-and-petroleum-products/use-of-oil.php>.

3, *Energy*, of this EIS, Section III.D of the final rule preamble, Chapter 5 of the Final TSD, Chapter 8 of the FRIA, and the Clean Grid Docket Memo, which is included in the rulemaking docket (Docket No. NHTSA-2023-0022).

Response

NHTSA has reviewed the references provided by the commenter and has added relevant information to the discussion of health impacts in Appendix C, *Air Quality*, of the Final EIS, as appropriate.

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

In addition, other forms of air pollution inherent in fossil fuel emissions pose a widespread and persistent problem in our States and Cities. Criteria pollutants (including fine particulate matter (PM_{2.5}) and ozone precursors) and air toxics negatively affect the health and welfare of people living in our

States and Cities, and some contribute to climate change.⁴⁷ In 2020, more than 30.7 million Americans breathed air with elevated levels of PM2.5 pollution for more than 100 days, and an additional 175.4 million Americans breathed air with elevated levels of PM2.5 for at least 31 days.⁴⁸ Millions also breathed air with elevated levels of ozone for more than 100 days.⁴⁹ Even air containing levels of PM2.5 and ozone below current federal air quality standards is harmful to public health.⁵⁰

Response

NHTSA agrees that poor air quality adversely affects human health. This Final EIS shows that increasing the fuel economy of the passenger car, light truck, and HDPUV fleet, such as by implementing the Preferred Alternative, would result in public health and climate benefits, which are analyzed in this Final EIS. Additional discussion of how NHTSA modeled these benefits and the results of NHTSA's modeling are provided in Chapter 5 of the TSD and Chapter 8 of the FRIA.

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

Various locations throughout our States and Cities have been unable to attain, or face difficulty maintaining, the NAAQS—designed to protect public health—for ozone.⁵¹ 42 U.S.C. § 7409(b). For example, multiple counties in California are registering serious, severe, or extreme nonattainment with the 8-Hour Ozone NAAQS. Similarly, several counties in the Metropolitan New York-New Jersey-Connecticut area are in severe nonattainment with the 2008 8-Hour Ozone NAAQS and are in moderate nonattainment with the 2015 8-Hour Ozone NAAQS.⁵²

A major precursor of ozone is VOCs.⁵³ The Preferred Alternative and the more stringent alternatives would result in decreases of VOC emissions as early as 2035. 88 Fed. Reg. at 56,324. While States have taken action to reduce VOC emissions from mobile and stationary sources, including power plants and

refineries, in an attempt to attain the NAAQS,⁵⁴ more stringent fuel economy standards would further help all States attain and maintain the ozone NAAQS.

Response

NHTSA agrees that increasing the fuel economy of the passenger car, light truck, and HDPUV fleet would result in public health and climate benefits, which are analyzed in this Final EIS. Additional discussion of how NHTSA modeled these benefits and the results of NHTSA's modeling are provided in Chapter 5 of the TSD and Chapter 8 of the FRIA.

In this Final EIS, NHTSA projects that the technologies that vehicle manufacturers would use to comply with the CAFE and HDPUV FE standards could reduce some emissions. However, NHTSA does not have authority to regulate emissions. EPA has authority to regulate emissions, which it exercises through setting emissions standards and other activities. On March 20, 2024, EPA announced final standards to further reduce harmful air pollutant emissions from LD and medium-duty vehicles starting with MY 2027 (EPA 2024g). This final rule builds upon EPA's GHG standards for passenger cars and light trucks for MYs 2023–2026 and leverages advances in clean car technology to unlock benefits to Americans ranging from improving public health through reducing smog- and soot-forming pollution from vehicles, to reducing climate pollution, to saving drivers money through reduced fuel and maintenance costs. These standards will phase in over MYs 2027–2032.

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

Wildfires pose significant public health risks due to air quality degradation.⁵⁵ Exposure to wildfire smoke may cause respiratory morbidity, especially exacerbations of asthma and chronic obstructive pulmonary disease.⁵⁶ “[W]ildfire-specific PM_{2.5} is up to 10 times more harmful on human health than PM_{2.5} from other sources.”^{57,58} This public health concern grows as the frequency and intensity of wildfires increase and is not limited to States where the wildfires are burning. The rising heat from the wildfires takes particulate matter and toxic gases in the smoke into the jet stream, which can carry those hazardous substances thousands of miles and cause harmful air pollution across the country. During the 2020 wildfire season and again in July of 2021, smoke from wildfires burning on the West Coast caused New

⁵⁴ Footnote 167: See, e.g., N.J. Dep't of Env't Prot., New Jersey SIP Revision for the Attainment and Maintenance of the Ozone NAAQS (Dec. 2017), at x, 4-14, <https://dep.nj.gov/wp-content/uploads/airplanning/8HrOzoneSIP2017-FinalSIP.pdf>.

⁵⁵ Footnote 65: IPCC Report 2022, *supra* note 34, at 1949.

⁵⁸ Footnote 68: Smoke from wildfires has also been found to exacerbate risks associated with the COVID-19 virus, and one study found that “[t]housands of COVID-19 cases and deaths in California, Oregon, and Washington between March and December 2020 may be attributable to increases in fine particulate air pollution (PM_{2.5}) from wildfire smoke.” Karen Feldscher, Link between wildfires and COVID cases established, THE HARV. GAZETTE (Aug. 13, 2021), <https://news.harvard.edu/gazette/story/2021/08/wildfire-smoke-linked-to-increase-in-covid-19-cases-and-deaths/>.

York City to experience some of the worst air quality in the world.⁵⁹ And in June 2023, New York City was once again blanketed in smoke, resulting in the highest measurements of 2.5 micron particles since recording began in 1999.⁶⁰ The combination of fierce wildfires in Canada and airflow patterns prompted the U.S. National Weather Service to issue air quality alerts for most of the Atlantic seaboard.⁶¹

Response

NHTSA agrees that wildfires can pose significant public health risks due to air quality degradation. Section 7.2.5, *Communities Facing Climate Change Effects*, of this Final EIS notes that higher average temperatures and drought induced by climate change can increase the occurrence of wildfires and the associated health risks. Additional discussion of how climate change is exacerbating wildfires is provided in Appendix F, *Greenhouse Gas Emissions and Climate Change*.

B.3.1.1 Analysis Methods

Comment

Comment Number: NHTSA-2022-0075-0030

Commenter: Roselie Bright

For most of the pollutants, the model relies on other federal reviews, the most recent one having been published in 2021. We all know that federal reports involve extensive approval time periods before publication. Therefore, there was probably at least a year of significant publications that weren't reviewed for this DEIS. There has been a steep rise in the number of emissions epidemiology publications in recent years. Therefore, I strongly suggest an update to the DEIS and the public health effects model using recent literature.

Response

NHTSA has reviewed the references provided by the commenter and has added relevant information to the discussion of health impacts in Appendix C, *Air Quality*, of the Final EIS, as appropriate.

B.3.2 Environmental Consequences

Comment

Comment Number: NHTSA-2022-0075-0032

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

The DEIS must account for the fact that new ZEVs will increase particulate matter ("PM") emissions through increased tire and road wear. EPA's National Emissions Inventory shows that roadway dust

⁵⁹ Footnote 69: See, e.g., Oliver Milman, New York air quality among worst in world as haze from western wildfires shrouds city, THE GUARDIAN (Jul. 21, 2021), <https://www.theguardian.com/us-news/2021/jul/21/new-york-air-quality-plunges-smoke-west-coast-wildfires>.

⁶⁰ Footnote 70: Aatish Bhatia et al., Just How Bad Was the Pollution in New York?, N.Y. TIMES (Jun. 9, 2023), <https://www.nytimes.com/interactive/2023/06/08/upshot/new-york-city-smoke.html>.

⁶¹ Footnote 71: Tyler Clifford, US East Coast blanketed in veil of smoke from Canadian fires, REUTERS (Jun. 8, 2023), <https://www.reuters.com/business/environment/us-states-under-air-quality-alerts-canadian-smoke-drifts-south-2023-06-07/>; see Julie Bosman, Smoky Air From Canadian Wildfires Blankets Midwestern Skies, N.Y. TIMES (Jun. 27, 2023), <https://www.nytimes.com/2023/06/27/us/midwest-chicago-smoke-air-quality.html>.

contributes more PM_{2.5} emissions than the tailpipe. Roadway dust emissions, including particles from tire wear, are correlated with vehicle weight, so increases in fleet average vehicle weight would be expected to increase roadway dust PM_{2.5} emissions.⁶² Converting ICEVs to ZEVs would significantly increase the average vehicle weight on U.S. roadways, which in turn would increase highway wear and entrained road dust emissions. Additionally, more limited carrying capacity of HDPUVs could require a greater number of ZEVs to move the same tonnage of cargo, thus increasing the number of vehicles needed to haul the same amount of cargo, vehicle miles traveled, and resulting PM emissions.⁶³

Response

NHTSA agrees that, to the extent that zero-emission vehicles (ZEVs) weigh more than ICE vehicles and that tire technologies remain constant, increases in the number of ZEVs could increase particulate matter (PM) emissions through increased tire and road wear. The CAFE Model accounts for PM emissions from tire wear when vehicles shift from one weight class to another but does not account for increases or decreases in vehicle weight within a class of vehicles when calculating the impact of brake and tire wear emissions. This is consistent with the EPA MOVES4 model that provided the emissions factors used in the CAFE Model. NHTSA will continue to examine literature and data on this topic for incorporation for future analysis. Additional discussion of how NHTSA estimates brake and tire wear is provided in Final TSD Chapter 5 and Section III of the final rule preamble.

NHTSA disagrees that battery electric vehicle (BEV) HDPUVs have a more limited carrying capacity than their ICE counterparts and that an increasing number of BEV HDPUVs would result in more VMT (and, thus, increasing PM emissions). NHTSA examined HDPUV BEV configurations in conjunction with Argonne National Laboratory prior to finalizing inputs for the CAFE Model analysis and does not believe that battery pack sizes will limit cargo capacity for HDPUVs (as opposed to what may be seen for larger medium and heavy-duty [MDHD] vehicles). This is especially true with the relatively lower ranges needed for HDPUV delivery vehicles, which generally operate in a more limited spatial area (as opposed again to the long-distance requirements for larger MDHD vehicles, which would require a larger battery pack). To reflect these considerations, NHTSA only modeled two HDPUV range configurations for HDPUV BEVs (termed “BEV1” and “BEV2”). In addition, NHTSA has limited the adoption of BEV powertrains for pickup trucks with high work factors. Additional discussion of how and why NHTSA modeled particular HDPUV BEV configurations is provided in Section III.D of the final rule preamble.

B.3.2.1 Cumulative Impacts

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

(1) Reducing Criteria Pollutant Emissions Will Benefit Public Health

NHTSA anticipates significant reductions of carbon monoxide emissions under all action alternatives, which could be so significant that it “could lead to changes in ambient pollution concentrations.” 88 Fed.

⁶² Footnote 30: EPA, “2020 National Emissions Inventory (NEI) Data,” available at <https://www.epa.gov/air-emissionsinventories/2020-national-emissions-inventory-nei-data>.

⁶³ Footnote 31: For further environmental impacts inadequately considered by the Agency, see AFPM’s comments on the Proposed Rule, incorporated by this reference herein.

Reg. at 56,323, 56,234. NHSTA also anticipates reductions in the emission of volatile organic compounds (“VOCs”) in the year 2035 and reduced PM2.5 and NOx emissions in the year 2050. *Id.*⁶⁴ The health benefits associated with a reduction in PM2.5 and ozone pollution are well-documented.⁶⁵ Short- and long-term PM2.5 exposures result in increased mortality risk and adverse cardiovascular and respiratory effects.⁶⁶ In California alone, over 5,000 premature deaths and hundreds of illnesses and emergency room visits for respiratory and cardiovascular disease are linked to PM2.5 pollution annually.⁶⁷ And long-term exposure to even very low PM2.5 levels (3µg/m³) may still lead to lower life expectancy for both men and women.⁶⁸ Studies have also demonstrated that particle pollution may significantly reduce lung function growth in children and that these effects are likely permanent.⁶⁹

Ozone pollution leads to similar negative health effects, especially for respiratory health.⁷⁰ Multiple epidemiological studies have shown that both short- and long-term exposures to ozone with median or average levels near or below the current 8-hour National Ambient Air Quality Standards (NAAQS) were

⁶⁴ Footnote 146: NHTSA anticipates that the reduction in VOC emissions in 2035 would occur in connection with all action alternatives. 88 Fed. Reg. at 56,323. The reduction in PM2.5 emissions in 2050 would occur in connection with all action alternatives. *Id.* The reduction of NOx emissions in 2050 would only occur in connection with the Preferred Alternative (PC2LT4) and PC1LT3. *Id.*

associated with adverse health outcomes, including lung function decline, increases in childhood asthma onset, preterm births, increased emergency room visits, and premature mortality.⁷¹

Additionally, elevated pollution levels have been linked to increased vulnerability to illnesses. In California, research has demonstrated a link between chronic exposure to elevated PM2.5 levels and increases cases of premature death and illness from COVID-19.⁷² At least one study determined that if all areas of California had PM2.5 below current federal air quality standards, a total of 4,250 COVID-19 deaths might have been prevented during the time period of the study.⁷³

The transportation sector is a major contributor to these health impacts because it is one of the largest emitters of PM2.5 and ozone precursors in the United States.⁷⁴ Moreover, it has long been acknowledged that people living, working, and attending school near major roadways face greater air pollution exposure.⁷⁵ See, e.g., 77 Fed. Reg. 62,624, 62,907 (Oct. 15, 2012); 75 Fed. Reg. 25,324, 25,504 (May 7, 2010). In some urban areas, gasoline-powered highway vehicles, diesel-powered highway vehicles, and other fossil-fuel-engine-driven sources (e.g., ships, aircraft, construction, and agricultural equipment), account for 13% to 30% of the total primary PM2.5 emissions.⁷⁶ In California, more than half of the PM2.5 pollution is produced by these mobile sources.⁷⁷ As described above, these emissions contribute to and exacerbate asthma, impair lung function, and increase cardiovascular mortality.⁷⁸ In Philadelphia, for example, some of the most polluted areas are along major highways or zones with heavy traffic, and the most polluted zip codes also have the largest number of lung cancer patients.⁷⁹ Traffic-related air pollution is especially harmful because it not only exacerbates asthma but may also

cause more people to become asthmatic.⁸⁰ Mobile sources are also the number one contributor to high ozone levels in the Ozone Transport Region.⁸¹

Response

NHTSA agrees that poor air quality adversely affects human health. This Final EIS shows that increasing the fuel economy of the passenger car, light truck, and HDPUV fleet, such as by implementing the Preferred Alternative, would result in public health and climate benefits, which are analyzed in this Final EIS. Additional discussion of how NHTSA estimated these benefits and additional results are provided in Chapters 5 and 6 of the TSD, and Chapter 8 of the FRIA.

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

Each action alternative considered in NHTSA’s proposal would result in reductions of air toxics emissions. 88 Fed. Reg. at 56,324. Reductions in air toxics emissions will benefit public health and welfare, in part because these emissions are known to cause cancer and other serious health effects.⁸²

New Jersey, for example, will benefit from the reduction of air toxics emissions anticipated by NHTSA because mobile sources are the largest contributors of air toxics emissions in the state.⁸³ In Allegheny County in Pennsylvania, mobile sources account for over 9% of the estimated cancer risk from air toxics emissions, mostly due to gasoline-powered cars.⁸⁴ The City of Richmond in California, with five petroleum refineries nearby and residents facing disproportionately high rates of cancer and other health impacts from air pollution, serves as another example of an area that will benefit from a reduction in air toxics emissions.⁸⁵

Response

NHTSA recognizes that air pollutants contribute to human health effects and agrees that increasing the fuel economy of the passenger car, light truck, and HDPUV fleet will result in public health benefits,

B.4 Greenhouse Gas Emissions and Climate Change

B.4.1 Affected Environment

B.4.1.1 Social Cost of Greenhouse Gas Emissions

Comment

Comment Number: NHTSA-2023-0022-25908

Commenter: Robert Tomiak

Organization: United States Environmental Protection Agency

The EPA's primary concern is that the draft EIS contains no estimates of the social cost of greenhouse gases (SC-GHG) for the baseline no-action and alternatives evaluated. EPA recommends that calculation and monetization estimates of SC-GHG, as well as a discussion on those estimates be included in the Final EIS. Current CEQ guidance is clear that these estimates should appear in the EIS.⁸⁶ The current EIS only makes a brief reference to the SC-GHG on page 5-7, where the accompanying RIA SC-GHG results are cited. Although the emissions estimates appear in the EIS, their corresponding monetization using the SC-GHG should also be presented and discussed to provide additional impact disclosure context for the emissions estimates.

Response

While NEPA does not require agencies to incorporate monetized values in environmental analyses, a monetized analysis like the social cost of carbon (SC-CO₂) offers a potential opportunity to contextualize environmental effects of an action to enhance the understanding of the public and decision-makers. As such, NHTSA has integrated an SC-CO₂ analysis in all recent CAFE EISs, either explicitly or through incorporation by reference to other rulemaking documents. Council on Environmental Quality regulations encourage agencies to incorporate by reference material to cut down on bulk and to combine documents to reduce duplication. As discussed in Section 5.3.2, *Social Cost of Greenhouse Gas Emissions*, the SC-CO₂ analysis in Section III.G.2.(b)(1) of the preamble to the final rule and Chapters 8.2.4 and 8.3.4 of the FRIA are incorporated in this EIS by reference. This information is available to the decision-maker and the public contemporaneously with the availability of this Final EIS, and the decision-maker had the opportunity to consider this information as part of the official record. Because one of the primary purposes of NHTSA's FRIA is to monetize and compare the potential costs and benefits of the Proposed Action and alternatives for the benefit of the decision-maker and the public, NHTSA believes that is the appropriate place for this analysis.

⁸⁶ Footnote 1: For information on current CEQ guidance, see https://ceq.doe.gov/guidance/ceq_guidance_nepa-ghg.html. Additional guidance also appears in <https://www.whitehouse.gov/briefing-room/statements-releases/2023/09/21/fact-sheet-biden-harris-administration-announces-new-actions-to-reduce-greenhouse-gas-emissions-and-combat-the-climate-crisis/>.

B.4.2 Environmental Consequences

B.4.2.1 Health, Societal, and Environmental Impacts of Climate Change

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

Globally, “[t]he past nine years have been the warmest years since modern recordkeeping began in 1880;”⁸⁷ and nine of the warmest eleven years on record in the United States have occurred since 2012.⁸⁸ There is a “virtually certain” chance that 2023 will rank among the ten warmest years on record, with a 93% chance it will rank among the top five.⁸⁹ The IPCC has determined that GHG emissions from human activities are already responsible for about 1.1°C of warming since 1850-1900⁹⁰ and that “[h]uman influence has warmed the climate at a rate that is unprecedented in at least the last 2000 years.”⁹¹

As temperatures rise, threats to public health and the environment in our States and Cities continue to mount. For example, extreme heat events are happening more frequently, with more intensity,⁹² and for longer duration.⁹³ In June 2021, a four-day heat wave across the Pacific Northwest set heat records all over the region, including heat so intense that roads buckled.⁹⁴ The region experienced 600 excess deaths during the heat wave.⁹⁵ In September 2022, a historic heat wave punished California, breaking high-temperature records in Northern California; it was considered “extraordinary” in part because of its

⁹⁵ Footnote 37: Nadja Popovich & Winston Choi-Schagrin, Hidden Toll of the Northwest Heat Wave: Hundreds of Extra Deaths, N.Y. TIMES (Aug. 11, 2021), <https://www.nytimes.com/interactive/2021/08/11/climate/deaths-pacific-northwest-heat-wave.html>. Although Washington only reported 95 heat-caused deaths at the time of reporting and Oregon reported 96, these figures do not include all impacts of extreme heat.

“mind-blowing duration.”⁹⁶ Extreme heat events like these are “likely to become the new normal.”⁹⁷ By 2053, the number of U.S. counties experiencing at least one day with a heat index above 125 degrees Fahrenheit is projected to increase from 50 to over 1,000.⁹⁸

Extreme heat events threaten not only our quality of life, but our lives themselves.⁹⁹ As temperatures rise, heat-related mortality is expected to increase, particularly in urban areas.¹⁰⁰ One study found that by 2100, annual heat-related deaths in the United States are projected to increase from 12,000 to 36,000 in a moderate-warming scenario or 97,000 in a high-warming scenario.¹⁰¹ Another study predicted that by 2080 to 2099, hospital admissions for heat-related respiratory diseases in New York state will be 2 to 6 times higher than in 1991 to 2004.¹⁰² A third study concluded that extreme heat days were associated with higher all-cause mortality rates in the contiguous United States, and disproportionately affected some subgroups, including older adults and Black adults.¹⁰³ On a global scale, new research indicates that for every 0.1 degree Celsius above present levels, about 140 million additional people will be exposed to dangerous levels of heat.¹⁰⁴

Response

Final EIS Chapter 5, *Greenhouse Gas Emissions and Climate Change*, and Appendix F, *Greenhouse Gas Emissions and Climate Change*, discuss observed and projected trends in several climate change attributes, including the increase in average and extreme temperatures in the United States and across various regions of the globe. To highlight these trends, the Final EIS incorporates information from the latest Sixth Assessment Reports of the Intergovernmental Panel on Climate Change (IPCC) as well as the Fifth National Climate Assessment (NCA5) of the United States Global Change Research Program

(USGCRP) which was released after the development of the Draft EIS. NHTSA agrees that the frequency of heat wave events in the United States has increased in the last few decades and that extreme heat events can adversely affect human health, food systems, and urban infrastructure. For a discussion on observed and projected trends in extreme temperature, readers can refer to Appendix F, Section F.3.1.1, *Temperature*, and Section F.5.2, *Sectoral Impacts of Climate Change*, of the Final EIS for more details on impacts of extreme heat on sectors including human health, food systems, and urban areas.

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

(2) Wildfires

Global warming is likely responsible for 70% to 88% of the atmospheric conditions fueling wildfires.¹⁰⁵ It engenders warm and dry conditions,¹⁰⁶ which have contributed to more extreme wildfires.¹⁰⁷ Since the 1970s, the wildfire season in the western United States has extended from 5 months to over 7 months long.¹⁰⁸ In the coming decades, climate change is projected to further increase fire activity across North America.¹⁰⁹

The annual numbers of large wildland fires and area burned in the western United States have risen in the past several decades,¹¹⁰ and the last few years have seen numerous record-setting wildfires. For example, in August 2023, Maui, Hawaii experienced one of the deadliest wildfires in United States history.¹¹¹ Multiple large wildfires also burned hundreds of thousands of acres in Colorado in July and

¹⁰⁵ Footnote 47: Alex Wigglesworth, Climate change is now the main driver of increasing wildfire weather, study finds, L.A. TIMES (Nov. 1, 2021), <https://www.latimes.com/california/story/2021-11-01/climate-change-is-now-main-driver-of-wildfire-weather>.

¹⁰⁶ Footnote 48: IPCC Report 2022, *supra* note 34, at 1948.

¹⁰⁷ Footnote 49: *Id.* at 1939.

¹⁰⁸ Footnote 50: U.S. Dep't of Agric., Wildfire, <https://www.climatehubs.usda.gov/taxonomy/term/398> (last accessed May 26, 2023).

¹¹⁰ Footnote 52: IPCC Report 2022, *supra* note 34, at 1948.

¹¹¹ Footnote 53: Stephen Culp, Maui Wildfires: What are the deadliest wildfires in US history?, REUTERS (Aug. 21, 2023), <https://www.reuters.com/world/us/maui-inferno-what-are-deadliest-wildfires-us-history-2023-08-13/>. Of the four wildfires on this list that occurred in the 21st century, and thus show the exacerbating effects of acute climate change, the Maui fires are the deadliest, with the other three all in California.

August 2020, including the second-largest fire in state history.¹¹² The largest wildfire in New Mexico history burned in 2022,¹¹³ destroying hundreds of homes.¹¹⁴

The increase in the number of wildfires is no longer limited to the western United States.¹¹⁵ For example, the year 2023 has been New Jersey's busiest fire season in more than a decade.¹¹⁶ New Jersey's Forest Fire Service has responded to 1,034 wildfires to-date in 2023, which have burned 17,979 total acres; fourteen of these wildfires burned in excess of 100 acres each and were considered to be major wildfires.¹¹⁷

California is uniquely vulnerable to wildfires,¹¹⁸ and the projected impacts on California from an increase in wildfire risk are severe. In 2018, the Camp Fire burned 155,366 acres of land, destroying 18,804 structures—roughly 90% of the homes in the town of Paradise—and killing 85 people;¹¹⁹ it was then the deadliest and most destructive wildfire in California history. In 2021, a record number of acres burned in the Sierra Nevada, breaking the previous record set in 2020.¹²⁰ The Dixie Fire, now the largest single wildfire in California history, also burned in 2021.¹²¹ As a result of climate change, the average annual area burned across California is projected to increase by around 77% by 2099, and the worst wildfire years could see burned area increases of more than 178% by the end of this century.¹²²

¹²² Footnote 64: ANTHONY WESTERLING, CAL. ENERGY COMMISSION, WILDFIRE SIMULATIONS FOR CALIFORNIA'S FOURTH CLIMATE CHANGE ASSESSMENT: PROJECTING CHANGES IN EXTREME WILDFIRE EVENTS WITH A WARMING CLIMATE 19 (2018).

Response

Final EIS Appendix F, *Greenhouse Gas Emissions and Climate Change*, discusses observed and projected trends in extreme weather events, including the increasing frequency and severity of wildfire events in the United States, particularly the western United States. To highlight these trends, the Final EIS incorporates information from the latest Sixth Assessment Reports of the IPCC as well as NCA5 of the USGCRP, which was released after the development of the Draft EIS. NHTSA agrees that higher average temperatures and drought induced by climate change may increase the occurrence of wildfires, and this poses significant risks to human health and safety. Acknowledging the adverse impacts from some of the recent wildfire events captured in this comment, NHTSA has updated Final EIS Appendix F, *Greenhouse Gas Emissions and Climate Change*, with information on more recent events, including the August 2023 wildfires in Hawaii. For a discussion on observed and projected trends in wildfires, readers can refer to Final EIS Appendix F, Section F.3.2, *Increased Incidence of Severe Weather Events*, and Section F.5.2, *Sectoral Impacts of Climate Change*, for impacts of wildfire events on air quality degradation and human health.

B.5 Life-Cycle Assessment (LCA) Implications of Vehicle Materials

B.5.1 Raw Material Extraction through Vehicle Assembly

B.5.1.1 Non-Battery Components

Comment

Comment Number: NHTSA-2022-0075-0032

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

Other areas where the DEIS fails to fully account for environmental impacts include:

Underestimating the need for aluminum, which involves a highly energy intensive production process, that is needed to light-weight substantially heavier EVs.¹²³ Using flawed cost and performance assumptions that overestimate EV adoption and fleet turnover, NHTSA's analysis overstates its calculated emissions benefits.¹²⁴

Response

NHTSA agrees that the demand for and production of aluminum will likely increase as part of manufacturing more energy-efficient vehicles for MYs 2027 and beyond. NHTSA has expanded on the projected aluminum demand for LD vehicles and HDPUVs in the discussion in Final EIS Section 6.2.1.3, *Aluminum*. The additional language includes information on the projected gross demand for aluminum until 2030 and the continued trend in American consumer preference towards larger cars.

Section 6.2.1.3, *Aluminum*, summarizes the available literature on the life cycle and environmental impacts of substituting aluminum for conventional steel components in vehicles. NHTSA finds there are

¹²³ Footnote 26: DEIS at 6-17 to 6-21.

¹²⁴ Footnote 27: See AFPM Comments at 67; and Trinity Report (Attachment B) at 12-15.

net energy and GHG reductions over the vehicle life cycle when substituting conventional steel with lighter-weight aluminum.

B.5.1.2 Battery Components

Comment

Comment Number: NHTSA-2022-0075-0032

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

Finally, citing a 2013 EPA study, the DEIS provides a scant discussion of resource depletion associated with the vast amount of mining that will be required to produce EVs that meet these stringent standards, and neglects to even mention that vast amount of resources needed to provide reliable and affordable electricity generation, transmission, and distribution, as well as charging infrastructure needed to support this EV mandate.¹²⁵ NHTSA must evaluate the “irreversible or irretrievable commitments of resources that would be involved in the proposal should it be adopted.”¹²⁶

Response

As stated several times throughout the Final EIS and the associated rulemaking documents, NHTSA’s standards are performance-based and do not mandate the adoption of any particular technology. As an example, Chapter 4.1 of the FRIA states that “each manufacturer is free to identify a compliance strategy that makes the most sense given its unique combination of vehicle models, consumers, and competitive position in the various market segments.” The CAFE Model estimates a cost-effective pathway that manufacturers could take to meet the standards. However, that pathway is an estimate and does not represent an irreversible or irretrievable commitment of resources that manufacturers and suppliers will expend to meet the final standards.

NHTSA discusses the resources that will likely be needed to meet the energy and electricity demand of the mandate in Chapter 3, *Energy*. The chapter also includes discussion of various environmental impacts (e.g., land clearing, habitat loss, bird mortality) associated with the physical infrastructure of regional grids. Section 3.2.2, *Electricity*, summarizes the necessary expansion to the grid to accommodate the increase in EVs and BEVs. This section also notes that while the transportation sector is projected to have the highest growth in electricity demand driven by the increasing share of EVs, in the Energy Information Administration’s (EIA’s) Annual Energy Outlook Reference case, this growth is estimated at less than 1 percent annually until 2050 (EIA 2023a).

Chapter 6, *Life-Cycle Assessment Implications of Vehicle Materials*, notes that for BEVs, the use of low-carbon electricity for charging reduces the life-cycle GHG emissions below those of ICE vehicles (Pathak et al. 2022). Chapter 6 also clarifies that the reliance of lithium-ion batteries on critical mineral supplies presents other environmental concerns, such as those related to resource availability and mining, and increases the importance placed on recycling (Pathak et al. 2022). NHTSA has expanded on the discussion in Chapter 6 noting U.S. efforts to secure a stable critical mineral supply chain and invest in battery innovation and material recycling to reduce critical mineral extraction and included a reference to the recent report, *Securing Critical Materials for the U.S. Electric Vehicle Industry* (ANL 2024). The report outlines the availability of resources and supportive policies to secure the resources for battery

¹²⁵ Footnote 32: DEIS at 6-31.

¹²⁶ Footnote 33: 40 CFR §1502.16(a)(4) and 1502.16(a)(7).

manufacturing and also suggests the existence of sufficient global supply of battery minerals to meet U.S. demand through 2035.

B.5.2 Vehicle Disposal and Recycling

Comment

Comment Number: NHTSA-2022-0075-0032

Organization: American Fuel & Petrochemical Manufacturers (AFPM)

Other areas where the DEIS fails to fully account for environmental impacts include:

- Vehicle disposal and recycling. As discussed above, recycling and scrappage rates must reflect the useful life of batteries and the quantities that will be disposed of. While the DEIS goes to great lengths to detail ideas for battery recycling, at the end of the day, the DEIS must account for realistic disposal rates and the waste classification of EV batteries, as the Environmental Protection Agency's Office of Resource Conservation and Recovery issued guidance that under the Resource Conservation and Recovery Act (RCRA), lithium-ion batteries generally qualify as a "hazardous waste" at their end of life.
- While the DEIS goes to great lengths to discuss the potential for recycling EV batteries, NHTSA acknowledges recycling is limited due to cost and varying battery chemistries. Recent studies confirm that disposed batteries could contribute 250,000 metric tons of waste to landfills for every one million retired ZEVs, yet less than five percent of Li-ion batteries, the most common batteries used in ZEVs, are currently being recycled "due in part to the complex technology of the batteries and cost of such recycling."¹²⁷ The DEIS must address in more detail for the environmental impacts of waste batteries.
- Benchmark Mineral Intelligence forecasts that near-term recyclers are likely to use scrap material from the increasing number of gigafactories coming online versus used electric vehicle batteries. Scrap is anticipated to account for 78 percent of recyclable materials in 2025. Recycling ZEV batteries to recover high-value metals is still moving towards commercial scale. The majority of analysts are aligned that recycling will not become an integral supplier of raw materials until the 2030s, and at that point, only will provide approximately 20 percent of demand.¹²⁸

Response

NHTSA has updated its statement in Chapter 6, *Life-Cycle Assessment Implications of Vehicle Materials*, about the hazardous waste classification of lithium-ion batteries under the Resource Conservation and Recovery Act in accordance with a memorandum released by EPA on May 24, 2023. The memorandum states that "most lithium-ion batteries are likely hazardous waste at end of life." The memo

¹²⁷ Footnote 28: Kelleher Environmental, "Research Study on Reuse and Recycling of Batteries Employed in Electric Vehicles: The Technical, Environmental, Economic, Energy and Cost Implications of Reusing and Recycling EV Batteries", (September 2019) available at <https://www.api.org/oil-and-natural-gas/wellstoconsumer/fuels-and-refining/fuels/vehicle-technology-studies>; Gavin Harper, Roberto Sommerville, et al., NATURE, "Recycling lithium-ion batteries from electric vehicles" (Jan. 21, 2020) available at <https://www.nature.com/articles/s41586-019-1682-5>.

¹²⁸ Footnote 29: Benchmark Minerals Intelligence, "Battery production scrap to be main source of recyclable material this decade" (Sept. 5, 2022) available at <https://source.benchmarkminerals.com/article/battery-productionscrap-to-be-main-source-of-recyclable-material-this-decade>.

recommends that lithium-ion batteries be managed under the “streamlined hazardous waste management standards for universal waste” (EPA 2023i).

NHTSA revised Section 6.3.2, *Battery Disposal and Recycling*, to include additional information and references on the environmental impact of battery landfilling, including the potential spread of toxins from landfill leachate and emissions to air, soil, and water (Mrozik et al. 2021). The section already includes language on the use of scrap material as a feedstock for recycling and acknowledges the current low rates of lithium-ion battery recycling.

The Final EIS continues to include language on the benefits of battery recycling and the impacts of different recycling pathways along with the difficulties that the industry must overcome, including cost efficiency and other potential uses for batteries at end of life. Given the long lifespans of EV batteries and the anticipated influx of end-of-life batteries, various efforts by U.S. agencies are underway to improve battery recycling. NHTSA has expanded on the discussion in Chapter 6, noting that the Federal Government is prioritizing investment in research and development of EV battery recycling and secondary application of end-of-life EV batteries, projects that reduce battery recycling costs, advancements in innovation in battery recycling, and solutions to increase the circularity of the EV battery supply chain (DOE 2022g, 2023i, 2024b; Advanced Research Projects Agency—Energy 2024). EPA is also developing a report on battery collection best practices and voluntary labeling guidelines (EPA 2024e). Because more information on battery recycling will become available as more vehicles with batteries reach their ends of life, NHTSA will continue to follow this issue and incorporate any additional information in future analyses.

B.6 Environmental Justice

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

First, decreasing domestic demand for petroleum would decrease domestic income inequality by reducing oil prices. Changes in oil prices have important distributional effects between consumers of refined petroleum products and producers of oil. Higher gasoline prices result in significant costs for families in the United States, especially lower-income families, who spend a disproportionately large percentage of their household income on gasoline.¹²⁹ And while corporate profits in the U.S. petroleum industry would rise with higher prices, potentially resulting in net zero GDP impacts, this transfer of wealth would have detrimental effects on U.S. consumer well-being and would impose disproportionate economic burdens across income groups.¹³⁰ Importantly to our States and Cities,¹³¹

¹³⁰ Footnote 7: AEC Comment, supra note 6 at 10-11.

¹³¹ Footnote 8: For example, the Governor of New Jersey recently signed Executive Order 262, establishing the Wealth Disparity Task Force, the purpose of which is to combat long-standing wealth gaps based on race and ethnicity. Governor Philip D. Murphy, New Jersey, Exec. Order No. 262 (Sept. 14, 2021).

“the transfer of revenue from U.S. oil producers to U.S. oil consumers could have substantial benefits for the most economically disadvantaged, reducing income inequality”¹³²

Response

Final EIS Section 7.2.3, *Vehicle Ownership*, discusses the concept that lower-income families spend a disproportionately large percentage of their household income on gasoline. Readers may consult Chapters 4, 5, and 7 of the FRIA and Chapter 6 of the TSD, which are incorporated in this Final EIS by reference, for a more extensive description of economic and energy security impacts of this action.

B.6.1 Vehicle Ownership

Comment

Comment Number: NHTSA-2022-0075-0031

Commenter: Anonymous

The Biden administration has already implemented the elimination of incandescent light bulbs which has had the effect of lessening the lighting choices offered to American consumers. Notice: these new CAFE standards will similarly negatively affect the motor vehicle industry mirroring what the Biden administration has imposed on the lighting portion of the manufacturing sector. When my mother was learning to drive (1950's), a car was easily afforded by teenagers. When I learned to drive in the late eighties, most teens had to borrow cars from family members. Now, many cars are fifty thousand dollars or more. Only a small fraction of the American population can easily afford this amount of money to buy a vehicle. Now that the administration thru the Federal Reserve has started raising interest rates, even fewer Americans will be able to afford vehicles. Given the less than effective public transportation sector, denigrating the ability of Americans to afford vehicles seems short sighted.

Response

As part of its decision that the final standards are maximum feasible, NHTSA has considered the additional costs to consumers of manufacturers adding additional fuel economy technology to vehicles. For the final standards, the costs of additional technology are outweighed by the fuel savings to the consumer. However, as the commenter mentioned, there are multiple factors that determine the price of a vehicle. Additional discussion of vehicle affordability is provided in Section VI of the final rule preamble, and NHTSA's estimates of the costs and benefits of the standards are provided in Chapter 8 of the FRIA.

Final EIS Section 7.2.3, *Vehicle Ownership*, states that the standards are projected to make both new and used cars more affordable due to the value of added fuel savings realized over the lifetime of the vehicle, with particular savings for low-income households (NRC 2015). Research by Greene and Welch (2018) estimates \$8,000 in savings for the lowest-income group due to fuel economy advancements. Again, the projected increases in vehicle costs are projected to be outweighed by fuel savings, resulting in an overall benefit to low-income households.

B.6.2 Communities Facing Climate Change Effects

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

Climate change's impacts will continue to disproportionately fall on environmental justice communities.¹³³ Environmental justice communities experience more severe climate impacts and are more vulnerable as the climate crisis worsens.

Severe climate harms are already a reality for many environmental justice communities. Globally, the last nine years have been the nine hottest on record, and that trend is expected to continue.¹³⁴ Members of environmental justice communities tend to work in occupations with increased exposure to extreme heat, such as the agricultural, construction, and delivery industries.¹³⁵ Farmworkers die of heat-related causes at 20 times the rate of the rest of the U.S. civilian workforce.¹³⁶ Since 2005, the first year California began tracking the number of heat-related fatalities, 36% of California's heat-related worker deaths have been of farmworkers.¹³⁷ Similarly, although construction workers comprise only 6% of the national workforce, they account for 36% of heat-related deaths.¹³⁸

In California, environmental justice communities suffer disproportionate impacts from extreme heat because they are more likely to lack air conditioning, tree canopy, and greenspace. Environmental justice communities have less access to air conditioning, and are less able to pay the utility bills required

¹³³ Footnote 115: "Environmental justice" is defined by EPA as the "fair treatment and meaningful involvement of all people regardless of race, color, national origin or income with respect to development, implementation, and enforcement of environmental laws, regulations and policies." U.S. ENV'T PROT. AGENCY, EJ 2020 ACTION AGENDA: THE U.S. EPA'S ENVIRONMENTAL JUSTICE STRATEGIC PLAN FOR 2016-2020, EPA-300-B-1-6004, at 1 (Oct. 2016). For the purpose of this comment, the term "environmental justice community" refers to a community of color or community experiencing high rates of poverty that, due to past and/or current unfair and inequitable treatment, is overburdened by environmental pollution, and the accompanying harms and risks from exposure to that pollution because of past or current unfair treatment.

¹³⁴ Footnote 116: NASA Says 2022 Fifth Warmest Year on Record, Warming Trend Continues, *supra* note 29; IPCC 2021 Summary for Policymakers, *supra* note 22, at 5-8, 14.

¹³⁸ Footnote 120: Xiuwen Sue Dong et al., Heat-Related Deaths Among Construction Workers in the United States, 62 *AM. J. INDUS. MED.* 1047-57 (2019).

to run air conditioning units or fans.¹³⁹ In urbanized environments, pavement, cement, and other non-vegetated areas contribute to the heat island effect, in which built environments retain heat, causing daytime temperatures to be from 1°F to 7°F hotter than suburban and rural areas and nighttime temperatures to be 2°F to 5°F hotter.¹⁴⁰ The heat island effect is inequitably distributed—it is most extreme in lower-income communities and communities of color.¹⁴¹ Contributing to this effect is the lack of tree canopy and greenspace in environmental justice communities, often due to lower historical and ongoing investment. Indeed, tree canopy and greenspace is highly correlated with historical redlining practices, in which federal housing policy directed investment away from lower-income communities, and especially communities of color, characterized as “risky” for loan servicing.¹⁴² Moreover, an EPA report found that individuals with lower incomes and individuals of color are respectively 11% to 16% and 8% to 14% more likely to live in areas with the highest projected increases in premature mortality from extreme heat.¹⁴³

In addition, flooding and drought from extreme weather events disproportionately affect environmental justice communities, and the inequity will grow as climate impacts worsen. Due to disinvestment, environmental justice communities often lack sufficient infrastructure to control flooding or ensure steady water supplies.¹⁴⁴ They also suffer from more severe impacts, such as contaminated water from pollutant flows during floods and increased concentration of contaminants during droughts.¹⁴⁵ EPA has also determined that individuals with lower incomes are more likely to live in areas with the highest projected land losses from sea level rise inundation and are more likely to face substantial traffic delays due to climate-driven changes in high-tide flooding.¹⁴⁶ Similarly, census tracts with predominantly tribal

communities, older adults, and low-income populations in California have been found to be more likely to be highly impacted by wildfires.¹⁴⁷

The above impacts especially apply to tribal communities. Due to land dispossession and forced migration, tribal communities are more exposed to extreme heat and more likely to rely on local water sources that are less resilient to drought and more contaminated.¹⁴⁸ Beyond those impacts, tribal communities also suffer cultural harms from the decimation or harm to local ecosystems and species of particular meaning to cultural practices.¹⁴⁹ These cultural resources have intrinsic value, and they are also critical to tribal community identity and group cohesion, which translates into direct health benefits.¹⁵⁰ Moreover, degradation of these cultural resources threatens traditional ecological knowledge, such as particularized understanding of local ecosystems, agriculture, and sustainable practices, that can help limit the impacts of climate change.¹⁵¹ Tribal communities with sovereign land holdings are also more vulnerable to climate impacts because they are unable to relocate.¹⁵²

Furthermore, environmental justice communities, including tribal communities, are environmentally overburdened due to greater existing pollution exposure.¹⁵³ This disadvantage manifests in higher rates of chronic disease, premature death, and other adverse public health outcomes.¹⁵⁴ Compounding these disparities, residents of environmental justice communities also have less access to health care—they are less likely to have health insurance and less likely to be able to afford necessary tests and procedures, and health care facilities are poorly staffed and equipped.¹⁵⁵ Consequently, residents of environmental justice communities are less able to withstand climate impacts that further damage their health, such as increased local smog conditions.¹⁵⁶

In addition to being more vulnerable to the impacts of climate change, environmental justice communities endure structural disadvantages that blunt their ability to adapt to a changing climate. Environmental justice communities have less access to financial resources, such as income and wealth, which are critical to climate resilience.¹⁵⁷ More financial resources equate to more mobility, more ability

¹⁵⁷ Footnote 139: Id. at 39.

to spend (on utilities, health care, home adaptation, etc.) to reduce climate harms, and more safeguards (such as insurance) in the event of extreme climate events.¹⁵⁸ Environmental justice communities have higher rates of limited English proficiency, which can reduce access to climate resilience programs and increase vulnerability in extreme climate events due to an inability to understand public health information.¹⁵⁹ Social capital in the political process is critical to ensure environmental justice communities receive resources to increase climate resilience and to prevent further entrenching existing inequities.

Response

As described in Section 7.2.5, *Communities Facing Climate Change Effects*, NHTSA acknowledges that minority and low-income populations are disproportionately affected by climate change. Appendix F, *Greenhouse Gas Emissions and Climate Change*, provides additional discussion of health and societal impacts of climate change on vulnerable populations. Section 7.3.1.5, *Communities Facing Climate Change Effects*, and Chapter 5, *Greenhouse Gas Emissions and Climate Change*, describe the projected decrease in carbon dioxide emissions from passenger cars and light trucks as a result of the Proposed Action and alternatives.

Comment

Comment Number: NHTSA-2022-0075-0033

Organization: California Office of the Attorney General et al. (States and Cities Joint Comment)

The projected positive impacts of NHTSA’s proposed standards are likely to be magnified in communities with higher percentages of Black, Asian American, and Latinx residents because refineries and major roadways are disproportionately located in those communities.¹⁶⁰ 88 Fed. Reg. at 56,317. For instance, nearly 700,000 people live within three miles of the seventeen refineries that reported actual annual benzene fence-line concentrations in 2020 above the level set by EPA that requires the refinery to take action to reduce emissions.¹⁶¹ Of these 700,000 people, 62% are African-American, Hispanic, Asian/Pacific Islander, or American Indian residents, and nearly 45% have incomes below the poverty level.¹⁶² As another example, the communities of Wilmington, Carson, and West Long Beach in Los Angeles, California are affected by pollution from major freeway junctions, as well as freight, port, and rail operations, oil and gas production, and five petroleum refineries.¹⁶³ A majority of those communities are considered disadvantaged under California law, scoring higher than the state average on key indicators of vulnerability, including criteria pollutant exposure, health status, and socio-economic criteria.¹⁶⁴ In the Northeast and Mid-Atlantic Region, average concentrations of exposures to PM2.5 are

¹⁶⁴ Footnote 176: Id. at 18-24.

75%, 73%, and 61% higher for Latinx residents, Asian American residents, and Black residents, respectively, than they are for white residents.¹⁶⁵ PM2.5 and NO2 concentrations are also highest for Black and Latinx communities in Massachusetts, in part because of their proximity to industrial facilities and highways, and these concentrations have increased even though overall exposure to those pollutants has decreased in Massachusetts.¹⁶⁶ Improvements in air quality anticipated by the Proposal will serve our States and Cities' environmental justice goals, by improving air quality in communities historically impacted by greater pollution.

Response

NHTSA agrees that improvements in air quality anticipated by the final rule will have a positive impact on environmental justice communities. Peer-reviewed sources the commenter cited are included in the Final EIS, including in the following sections:

- Section 7.2.1.1, *Proximity to Oil Production and Refining*, references data from the Environmental Integrity Project (2021) that found minority and low-income populations are more likely to experience refinery emissions exceeding EPA standards, particularly benzene concentrations.
- Section 7.2.2, *Proximity to High-Traffic Roadways*, includes updated text from a study (Rosofsky et al. 2018) that showed increased PM2.5 and nitrogen dioxide concentrations for Black and Latinx communities in Massachusetts.

In addition to the studies the commenter referenced, Section 7.2, *Affected Environment*, provides information on public health and vulnerable populations and references studies that were included in the 2021 EPA report on Climate Change and Social Vulnerability in the United States (EPA 2021c; Kiomourtzoglou et al. 2016; Di et al. 2017a; Tessum et al. 2021). From these studies, NHTSA included findings about the relationship between higher air pollution exposure and vulnerable populations (low-income individuals and people of color). NHTSA also included a finding from the 2019 EPA Integrated Science Assessment, which found that Black individuals are particularly exposed to health effects caused by PM2.5 (EPA 2019b). Section 7.2.5, *Communities Facing Climate Change Effects*, also incorporates a discussion on the increasing levels of PM2.5 and ozone concentrations due to climate change and the disproportionate exposure Black individuals have to PM2.5 (EPA 2021c).

B.7 Other Comments

Comment

Comment Number: NHTSA-2022-0075-0030

Commenter: Roselie Bright

2. To do this properly, the reviewer teams need to include scientists trained in environmental epidemiology. Appendix G lists people with environmental masters degrees, none with a public health emphasis. Evaluation of environmental epidemiology requires at least masters level training specifically in public health science. Please obtain an environmental epidemiologist to update the review of recent literature and extract important inputs into the public health effects model. Doing so might clear up some of my confusion for a few specific points:

Response

The team that developed both the Draft EIS and Final EIS has multiple members who are trained in and have decades of experience reviewing environmental epidemiology studies and related reports. NHTSA disagrees that a public health degree is necessary to evaluate epidemiology studies for environmental impacts relevant to the EIS. NHTSA has reviewed all literature that was cited by public commenters and has updated the EIS with discussions of and references to recent peer-reviewed and/or government reports, as appropriate.

APPENDIX C

Air Quality

APPENDIX C AIR QUALITY

C.1 Introduction

This appendix summarizes the criteria pollutants, toxics, vehicle standards, and conformity regulations that inform the affected environment for Chapter 4, *Air Quality*. Section C.2, *Health Effects of Criteria Pollutants*, Section C.3, *Health Effects of Mobile Source Air Toxics*, and Section C.4, *Vehicle Emissions Standards*, describe the environment and resource areas, including human health impacts, that are affected by NHTSA's CAFE standards for MY 2027 and beyond passenger cars and light trucks and fuel efficiency (FE) standards for MY 2030 and beyond heavy-duty pickup trucks and vans (HDPUVs). Section C.5, *Methods*, describes the methodology used for assessing air quality impacts. Chapter 2, *Proposed Action and Alternatives and Analysis Methods*, describes the Proposed Action and alternatives used in this analysis for the CAFE and HDPUV FE standards.

C.2 Health Effects of Criteria Pollutants

The following sections describe the health effects of the five criteria pollutants addressed in this EIS analysis. This information is adapted from EPA (2024e) unless otherwise noted by a citation to an individual study. The most recent EPA technical reports and *Federal Register* notices for National Ambient Air Quality Standards (NAAQS) reviews provide more information on the health effects of criteria pollutants (EPA 2020b, 2020c).

C.2.1 Ozone

Ozone is a photochemical oxidant and the major component of smog. Ozone is not emitted directly into the air but is formed through complex chemical reactions among precursor emissions of volatile organic compounds (VOCs) and nitrogen oxides (NO_x) in the presence of the ultraviolet component of sunlight. For short-term ozone exposures, a causal relationship exists with respiratory effects—including decreases in lung function, pulmonary inflammation, exacerbation of asthma, respiratory-related hospital admissions (e.g., for chronic obstructive pulmonary disease [COPD] and pneumonia; Medina-Ramón et al. 2006)—and respiratory-related mortality. A causal relationship likely exists with metabolic effects and complications due to diabetes, while evidence is suggestive of a causal relationship with impacts on the cardiovascular and central nervous systems and total mortality. For long-term ozone exposure, a causal relationship likely exists with respiratory effects (e.g., new onset asthma, pulmonary inflammation, and injury), and evidence is suggestive of a causal relationship with total mortality, as well as effects on the cardiovascular, metabolic, reproductive, developmental, and central nervous systems.

In addition to its human health impacts, ozone has the potential to affect the health of vegetation and ecosystems. Ozone in the atmosphere is absorbed by plants and disturbs the plant's carbon sequestration process, thereby limiting its available energy supply. Consequently, exposed plants can lose their vigor, become more susceptible to disease and other environmental stressors, and demonstrate reduced growth, visual abnormalities, or accelerated aging. Ozone can produce both acute and chronic injury in sensitive species, depending on the concentration level, the duration of the exposure, and the plant species under exposure. Because of the differing sensitivities among plants to ozone, ozone pollution can also exert a selective pressure that leads to changes in plant community composition.

VOCs, a chemical precursor to ozone, also can play a role in vegetation damage (National Park Service 2019). For some sensitive plants under exposure, VOCs have been demonstrated to affect seed production, photosynthetic efficiency, leaf water content, seed germination, flowering, and fruit ripening (Pinto et al. 2010). NO_x, the other chemical precursor to ozone, has also been demonstrated to affect vegetation health (Hu et al. 2015; Viskari 2000; Ugrekheldze et al. 1997; Kammerbauer et al. 1987; see comprehensive discussion in Appendix 3.3 of EPA 2020d). Most of the studies of the impacts of VOCs and NO_x on vegetation have focused on short-term exposure; few studies have focused on long-term impacts and the potential for the metabolites¹ of these compounds to affect herbivores or insects.

C.2.2 Particulate Matter

Particulate matter (PM) is a generic term for a broad class of chemically and physically diverse substances that exist as discrete particles. PM includes dust, dirt, soot, smoke, and liquid droplets directly emitted into the air, as well as particles formed in the atmosphere by condensation or by the transformation of emitted gases such as NO_x, sulfur oxides (SO_x), and VOCs. Fine particles are produced primarily by combustion processes and by these atmospheric transformations of emitted gases. The definition of PM also includes particles composed of elemental carbon (black carbon).² Gasoline-fueled and diesel-fueled vehicles emit PM.

In general, smaller PM penetrates deeper into the respiratory system. Exposure to PM with a diameter equal to or less than 2.5 microns (PM_{2.5}) has been associated with risk for several respiratory conditions, including COVID-19 (Poizzer et al. 2020; Wu et al. 2020; Zhou et al. 2021), and with increased mortality rates both in the population at large (Luo et al. 2022; Kheirbek et al. 2016) and in adult at-risk populations such as Medicaid-eligible individuals, women, and elderly individuals (Di et al. 2017a). In addition, Volk et al. have demonstrated associations between PM with a diameter equal to or less than 10 microns (PM₁₀), PM_{2.5}, and autism in children (Volk et al. 2013). For short-term PM_{2.5} exposures, there is a causal relationship with mortality, premature mortality, and cardiovascular effects (e.g., ischemic heart disease, heart failure, cardiovascular-related hospital admissions and emergency department visits), while there is likely to be a causal relationship with respiratory effects (e.g., asthma exacerbation in children, COPD exacerbation in adults, respiratory mortality), and the evidence is suggestive of (but not sufficient to infer) a causal relationship with metabolic effects and nervous system effects. For long-term PM_{2.5} exposures, there is a causal relationship with mortality, premature mortality, and cardiovascular effects (e.g., coronary heart disease, stroke, atherosclerosis, cardiovascular mortality), while there is likely to be a causal relationship with respiratory effects (e.g., development of COPD, increased asthma incidence and prevalence, wheeze in children, acceleration of lung function decline in adults, respiratory mortality), nervous system effects (e.g., reduced cognitive functions, reductions in brain volume in adults), and cancer (e.g., lung cancer), and the evidence is suggestive of (but not sufficient to infer) a causal relationship with reproductive effects, developmental effects, and metabolic effects. There is strong evidence of disparities in PM_{2.5} exposure and health

¹ Metabolites are formed as the initial compounds break down and are transformed through metabolism.

² Elemental carbon and black carbon are similar forms of fine PM and are considered synonymous for purposes of this analysis. The term *elemental carbon* describes carbonaceous particles based on chemical composition rather than light-absorbing characteristics. The term *black carbon* describes particles of mostly pure carbon that absorb solar radiation at all wavelengths (EPA 2012c). The carbon content of a sample of PM can be described by either term depending on the test method used: typically, the result for a sample tested by thermal or wet chemical methods is termed *elemental carbon* while the result for a sample tested by optical methods is termed *black carbon* (Long et al. 2013).

effects by race/ethnicity, particularly within Hispanic and non-Hispanic Black populations, and potentially for people of low socioeconomic status.

For PM with diameter between 2.5 and 10 microns, evidence for particular health effects is either suggestive of (but not sufficient to infer) a causal relationship or inadequate to determine the presence or absence of a causal relationship. Exposure to PM₁₀ has been associated with hospital admissions for chronic obstructive pulmonary disease and pneumonia (Medina-Ramón et al. 2006) and infant mortality rates (Knittel et al. 2016).

PM also can contribute to poor visibility by scattering and absorbing light, making the terrain appear hazy. To address visibility concerns, EPA developed the regional haze program,³ which was put in place in July 1999 to protect visibility in Mandatory Class I Federal Areas (national parks and wilderness areas). EPA has also set secondary NAAQS to regulate non-Class I areas outside the regional haze program. Deposition of PM (especially secondary PM formed from NO_x and SO_x) can damage materials, adding to the effects of natural weathering processes by potentially promoting or accelerating the corrosion of metals, degrading paints, and deteriorating building materials (especially concrete and limestone).

EPA classifies diesel particulate matter (DPM) as a mobile source air toxic (MSAT), so it is addressed in Section C.3.5, *Diesel Particulate Matter*.

C.2.3 Carbon Monoxide

Carbon monoxide (CO) is a colorless, odorless, poisonous gas produced by incomplete combustion of carbon in fuels. Motor vehicles are the single largest source of CO emissions nationally,⁴ though vehicle emissions of CO are reduced through newer engine technologies operating at higher temperatures. When CO enters the bloodstream, it acts as an asphyxiant by reducing the delivery of oxygen to the body's organs and tissues. It can affect the central nervous system and impair the brain's ability to function properly. For short-term CO exposures, there likely is a causal relationship with cardiovascular morbidity, while the evidence is suggestive of a causal relationship with central nervous system effects, respiratory morbidity, and mortality. For long-term CO exposures, the evidence is suggestive of a causal relationship with central nervous system effects and with developmental effects and birth outcomes, while there likely is not a causal relationship with mortality. High levels of postnatal exposure to CO have been shown to have an effect on infant mortality (Currie and Neidell 2005; Currie et al. 2009).

C.2.4 Sulfur Dioxide

Sulfur dioxide (SO₂), one of various oxides of sulfur, is a gas formed from combustion of fuels containing sulfur. Most SO₂ emissions are produced by stationary sources such as power plants. SO₂ is also formed when gasoline is extracted from crude oil in petroleum refineries and in other industrial processes. The EPA 2001 Highway Diesel Fuel Sulfur Control Requirements mandated that all highway diesel fuel be Ultra-Low Sulfur Diesel with sulfur content limited to 15 parts per million (ppm) after 2010, and the EPA

³ Final Rule: Regional Haze Regulations, 64 FR 35714 (July 1, 1999).

⁴ Highway motor vehicles overall accounted for approximately 30 percent of national CO emissions in 2021 (EPA 2022h). In 2023, passenger cars and passenger trucks are estimated to account for approximately 86 percent of the CO emissions from highway motor vehicles while HD pickup trucks and vans account for another 11 percent ("onroad_2016fh 2016fj 2023fh 2023fj 2026fj.xlsx" file from EPA 2022e).

Tier 3 Motor Vehicle Emission and Fuel Standards lowered the sulfur content of gasoline to 10 ppm starting in 2017. These standards have achieved large reductions in tailpipe SO₂ emissions (EPA 2024c).

For short-term exposure to SO₂, there is a causal relationship with respiratory health effects, including bronchoconstriction, decreases in lung function, and admissions to hospitals and emergency room visits (particularly in asthmatics), and there is evidence suggestive of a causal relationship with mortality. For long-term SO₂ exposures, it is challenging to separate impacts from SO₂ exposure and impacts from other co-emitted pollutants, but there is evidence suggestive of a causal relationship with respiratory effects, particularly childhood asthma. SO₂ also is a primary contributor to acidic deposition, or acid rain, which causes acidification of lakes and streams and can damage trees, crops, historic buildings, and statues.

C.2.5 Nitrogen Dioxide

Nitrogen dioxide (NO₂), a reddish-brown, highly reactive gas, is one of the oxides of nitrogen formed by high-temperature combustion (as in vehicle engines) of nitrogen and oxygen. Most NO_x created in the combustion reaction consists of nitric oxide (NO), which oxidizes to NO₂ in the atmosphere. While there is some evidence of other health effects due to exposure to NO₂, it is challenging to separate impacts from NO₂ exposure and impacts from other roadway pollutants. For short-term exposures to NO₂, there is sufficient evidence to infer a causal relationship with respiratory effects, particularly for asthma exacerbation, while the evidence is suggestive of (but insufficient to infer) a causal relationship with cardiovascular effects and mortality. For long-term NO₂ exposure, there likely is a causal relationship with respiratory effects (including asthma development in children), while the evidence is suggestive of (but insufficient to infer) a causal relationship with cardiovascular effects, diabetes, birth outcomes, and cancer. NO₂ from vehicle traffic has been associated with risk for several respiratory conditions, including COVID-19 (Lipsitt et al. 2021) and autism in children (Volk et al. 2013). Oxides of nitrogen are an important precursor to ozone and acid rain and can affect terrestrial and aquatic ecosystems.

C.3 Health Effects of Mobile Source Air Toxics

The following sections briefly describe the health effects of the six priority MSATs analyzed in this EIS. This information is adapted from EPA (2024e) unless otherwise stated. EPA has not established NAAQS for MSATs.

Motor vehicle emissions contribute to ambient levels of air toxics known or suspected to be carcinogens or known to have noncancer health effects. These compounds include, but are not limited to, acetaldehyde, acrolein, benzene, 1,3-butadiene, and formaldehyde. These five air toxics, plus DPM, are the six priority MSATs analyzed in this EIS. Most of these, except for DPM, were identified as national or regional risk drivers or contributors in the EPA 2018 and/or 2019 AirToxScreens and have significant inventory contributions from mobile sources (EPA 2023m). This EIS does not analyze polycyclic organic matter separately, but this matter can occur as a component of DPM and is discussed in Section C.3.5, *Diesel Particulate Matter*. Naphthalene also is not analyzed separately in this EIS, but it is a member of the polycyclic organic matter class of compounds discussed in Section C.3.5, *Diesel Particulate Matter*.

C.3.1 Acetaldehyde

Acetaldehyde is classified in the EPA Integrated Risk Information System (IRIS) database as a probable human carcinogen, based on nasal tumors in rats, and is considered toxic by the inhalation, oral, and intravenous routes (EPA 1998). In its Fifteenth Report on Carcinogens (National Toxicology Program

[NTP] 2021a), the U.S. Department of Health and Human Services “reasonably anticipates” acetaldehyde to be a human carcinogen, and the World Health Organization’s International Agency for Research on Cancer (IARC) classifies acetaldehyde as possibly carcinogenic to humans (Group 2B) (IARC 1999).

The primary noncancer effects of exposure to acetaldehyde vapors include eye, skin, and respiratory-tract irritation (EPA 1998, 2000b). In short-term (4-week) rat studies, degeneration of olfactory epithelium was observed at various concentration levels of acetaldehyde exposure (National Research Council Committee on Emergency and Continuous Exposure Guidance Levels for Selected Submarine Contaminants 2009). EPA used data from these studies to develop an inhalation reference concentration. Some asthmatics have been shown to be a sensitive subpopulation to decreases in functional expiratory volume and bronchoconstriction upon inhaling acetaldehyde (California Office of Environmental Health Hazard Assessment [OEHHA] 2014).

C.3.2 Acrolein

Acrolein is extremely acrid and is irritating to humans when inhaled, with acute exposure resulting in upper respiratory tract irritation, mucus hypersecretion, and congestion. The intense irritancy of this carbonyl compound has been demonstrated during controlled tests in human subjects, who suffer intolerable eye and nasal mucosal sensory reactions within minutes of exposure (EPA 2003a). The EPA 2003 IRIS human health risk assessment for acrolein (EPA 2003a) could not determine the potential carcinogenicity because at the time, the existing data were inadequate for an assessment of human carcinogenic potential for either the oral or inhalation route of exposure, but it summarizes studies regarding acute effects of human exposure to acrolein. Evidence from studies in humans indicate that levels as low as 0.09 parts per million (ppm) (0.21 milligram per cubic meter) for 5 minutes can elicit subjective complaints of eye irritation, with increasing concentrations leading to more extensive eye, nose, and respiratory symptoms (OEHHA 2014). Lesions to the lungs and upper respiratory tracts of rats, rabbits, and hamsters have been observed after subchronic exposure to acrolein (OEHHA 2014). Animal studies report acute exposure effects such as bronchial hyper-responsiveness (OEHHA 2014). In a 2017 study, the acute respiratory irritant effects of exposure to 4 ppm acrolein were more pronounced in mice with allergic airway disease compared to non-diseased mice, which also showed decreases in respiratory rate (Snow et al. 2017). Based on these animal data and demonstration of similar effects in humans (e.g., reduction in respiratory rate), individuals with compromised respiratory function (e.g., emphysema and asthma) are expected to be at increased risk of developing adverse responses to strong respiratory irritants such as acrolein.

IARC determined that acrolein was classifiable as “probably carcinogenic” with respect to its carcinogenicity in humans (IARC 2020; Lancet 2021).

C.3.3 Benzene

EPA’s IRIS database lists benzene as a known human carcinogen (causing leukemia) by all routes of exposure and concludes that exposure is associated with additional health impacts, including genetic changes in both humans and animals and increased proliferation of bone marrow cells in mice (EPA 2002a; IARC 2018). Data indicate a causal relationship between benzene exposure and acute lymphocytic leukemia and suggest a relationship between benzene exposure and chronic nonlymphocytic leukemia and chronic lymphocytic leukemia. IARC and the U.S. Department of Health and Human Services have characterized benzene as a human carcinogen (IARC 2018; NTP 2021b).

Several adverse noncancer health effects, including blood disorders such as preleukemia and aplastic anemia, have also been associated with long-term exposure to benzene (OEHHA 2014). The most sensitive noncancer effect observed in humans, based on current data, is depression of the absolute lymphocyte count in blood (OEHHA 2014; EPA 2003b). In addition, recent work, including studies sponsored by the Health Effects Institute (HEI), provides evidence that biochemical responses are occurring at lower levels of benzene exposure than previously known (OEHHA 2014).

C.3.4 1,3-Butadiene

EPA has characterized 1,3-butadiene as carcinogenic to humans through inhalation (EPA 2002b, 2002c). IARC has determined that 1,3-butadiene is a probable human carcinogen, and the U.S. Department of Health and Human Services has characterized 1,3-butadiene as a known human carcinogen (IARC 2012; NTP 2021c). Numerous experiments have demonstrated that animals and humans metabolize 1,3-butadiene into compounds that are genotoxic (capable of causing damage to a cell's genetic material such as deoxyribonucleic acid [DNA]). The specific mechanisms of 1,3-butadiene-induced carcinogenesis are not known; however, scientific evidence strongly suggests that the carcinogenic effects are mediated by genotoxic metabolites. Animal data suggest that females could be more sensitive than males to cancer effects associated with 1,3-butadiene exposure. There are insufficient data on humans from which to draw conclusions about sensitive subpopulations. 1,3-butadiene also causes a variety of reproductive and developmental effects in mice; there are no available human data on these effects. The most sensitive effect was ovarian atrophy observed in a lifetime bioassay of female mice (EPA 2002c).

C.3.5 Diesel Particulate Matter

Diesel exhaust consists of a complex mixture of carbon dioxide (CO₂), oxygen, nitrogen, water vapor, CO, nitrogen compounds, sulfur compounds, and numerous low-molecular-weight hydrocarbons. A number of these gaseous hydrocarbon components are individually known to be toxic, including aldehydes, benzene, and 1,3-butadiene. The DPM present in diesel exhaust consists mostly of fine particles (smaller than 2.5 microns), of which a significant fraction is ultrafine particles (smaller than 0.1 micron). These particles have a large surface area, which makes them an excellent medium for adsorbing organics, and their small size makes them highly respirable. Many of the organic compounds present in the gases and on the particles, such as polycyclic organic matter, are individually known to have mutagenic and carcinogenic properties (EPA 2002d).

DPM also includes elemental carbon (black carbon) particles emitted from diesel engines. EPA has not provided a special status, such as a NAAQS or other health-protective measure, for black carbon, but addresses black carbon in terms of PM_{2.5} and DPM emissions.

Diesel exhaust varies significantly in chemical composition and particle sizes between different engine types (HD, light-duty [LD]), engine operating conditions (idle, acceleration, deceleration), and fuel formulations (high-/low-sulfur fuel). Also, there are emissions differences between on-road and nonroad engines because the nonroad engines are generally older technology. After being emitted from the engine exhaust, diesel exhaust undergoes dilution, as well as chemical and physical changes in the atmosphere. The lifetime for some of the compounds present in diesel exhaust ranges from hours to days.

In EPA's 2002 *Diesel Health Assessment Document* (Diesel HAD) (EPA 2002d), exposure to diesel exhaust was classified as likely to be carcinogenic to humans by inhalation from environmental exposures, in

accordance with the revised draft 1996 to 1999 EPA cancer guidelines (EPA 1999). EPA published a review of diesel exhaust health effects in 2007 (Ris 2007). The assessment concluded that long-term inhalation exposure is likely to pose a lung cancer hazard to humans as inferred from epidemiologic and certain animal studies. A number of other agencies (National Institute for Occupational Safety and Health, IARC, World Health Organization, California EPA, and U.S. Department of Health and Human Services) have made similar hazard classifications.

Noncancer health effects of acute and chronic exposure to diesel exhaust emissions are also of concern. For example, Beatty and Shimshack (2011) found that diesel emissions from school buses exacerbate or cause asthma or bronchitis in children and adults, and they also linked diesel emissions to childhood pneumonia. EPA derived a diesel exhaust reference concentration from consideration of four well-conducted chronic rat inhalation studies showing adverse pulmonary effects. The reference concentration is 5 micrograms per cubic meter ($\mu\text{g}/\text{m}^3$) for diesel exhaust measured as DPM. This reference concentration does not consider allergenic effects such as those associated with asthma or immunologic effects or the potential for cardiac effects. There was emerging evidence in 2002, discussed in the Diesel HAD, that exposure to diesel exhaust can exacerbate these effects, but the exposure-response data were lacking at that time to derive a reference concentration based on these then-emerging considerations. The EPA Diesel HAD states, “With [DPM] being a ubiquitous component of ambient PM, there is an uncertainty about the adequacy of the existing [diesel exhaust] non-cancer database to identify all of the pertinent [diesel exhaust]-caused non-cancer health hazards.” The Diesel HAD also notes “that acute exposure to [diesel exhaust] has been associated with irritation of the eye, nose, and throat, respiratory symptoms (cough and phlegm), and neurophysiological symptoms such as headache, lightheadedness, nausea, vomiting, and numbness or tingling of the extremities.” The Diesel HAD notes that the cancer and noncancer hazard conclusions applied to the general use of diesel engines then on the market and, as cleaner engines replace a substantial number of existing ones, the applicability of the conclusions would need to be reevaluated.

The Diesel HAD also briefly summarizes health effects associated with ambient PM and discusses EPA’s then-annual PM_{2.5} NAAQS of $15 \mu\text{g}/\text{m}^3$. EPA revised the annual PM_{2.5} NAAQS to $12 \mu\text{g}/\text{m}^3$ in 2012, and to $9.0 \mu\text{g}/\text{m}^3$ in 2024. There is a large and extensive body of human data showing a wide spectrum of adverse health impacts associated with exposure to ambient PM, of which diesel exhaust is an important component. The PM_{2.5} NAAQS is designed to provide protection from the noncancer health effects and premature mortality attributed to exposure to PM_{2.5}. The contribution of diesel PM to total ambient PM varies in different regions of the country, within a region, and from one area to another. The contribution can be high in near-roadway environments, for example, or in other locations where diesel engine use is concentrated.

Since 2002, several new studies have continued to report increased lung cancer risk with occupational exposure to diesel exhaust from older engines. Of particular note since 2011, three new epidemiology studies have examined lung cancer in occupational populations; for example, in truck drivers, underground nonmetal miners, and other diesel-engine-related occupations (HEI 2015; Olsson et al. 2011). These studies reported increased risk of lung cancer with exposure to diesel exhaust with evidence of positive exposure-response relationships to varying degrees. These newer studies—along with others that have appeared in the scientific literature (e.g., Kim et al. 2018; Ilar et al. 2017)—add to the evidence EPA evaluated in the 2002 Diesel HAD and further reinforce the concern that diesel exhaust exposure likely poses a lung cancer hazard. The findings from these newer studies do not necessarily apply to newer technology diesel engines because the newer engines have large reductions in the emissions constituents compared to older-technology diesel engines.

In light of the growing body of scientific literature evaluating the health effects of exposure to diesel exhaust, in June 2012, IARC, a recognized international authority on the carcinogenic potential of chemicals and other agents, evaluated the full range of cancer-related health effects data for diesel-engine exhaust. IARC concluded that diesel exhaust should be regarded as “carcinogenic to humans” (IARC 2014; Silverman 2018). This designation was an update from its 1988 evaluation, which considered the evidence indicative of a “probable human carcinogen.”

C.3.6 Formaldehyde

In 1991, EPA concluded that formaldehyde is a carcinogen based on nasal tumors in animal bioassays (EPA 1991). EPA developed an inhalation unit risk for cancer and a reference dose for oral noncancer effects and posted them in the IRIS database. Since that time, NTP and IARC have concluded that formaldehyde is a known human carcinogen (NTP 2021d; IARC 2012).

The conclusions by IARC and NTP reflect the results of epidemiologic research published since 1991, in combination with previous animal, human, and mechanistic evidence. Research by the National Cancer Institute reported an increased risk of nasopharyngeal (nose and throat) cancer and specific lymphohematopoietic (lymph and blood) malignancies among workers exposed to formaldehyde (National Cancer Institute 2011). A National Institute of Occupational Safety and Health study of garment workers also reported increased risk of death due to leukemia among workers exposed to formaldehyde. Extended follow-up of a cohort of British chemical workers did not report evidence of an increase in nasopharyngeal or lymphohematopoietic cancers, but a continuing statistically significant excess in lung cancers was reported (Checkoway et al. 2015). Workers exposed to formaldehyde in pathology laboratories have been observed to experience increased genetic damage and alterations to various lymphocytes (Costa et al. 2019). Finally, a study of embalmers reported formaldehyde exposures to be associated with an increased risk of myeloid (bone marrow cell) leukemia but not brain cancer (Hauptmann et al. 2009).

Other health effects of formaldehyde were reviewed by the Agency for Toxic Substances and Disease Registry (ATSDR) in 1999 (ATSDR 1999) and supplemented in 2010 (ATSDR 2010), by the NTP (NIH 2011), and by the World Health Organization (World Health Organization 2002). These organizations reviewed the literature concerning effects on the eyes and respiratory system, the primary point of contact for inhaled formaldehyde, including sensory irritation of eyes, and respiratory tract, pulmonary function, nasal histopathology, and immune system effects. In addition, research on reproductive and developmental effects and neurological effects were discussed along with several studies that suggest formaldehyde may increase the risk of asthma, particularly in young people. EPA released a draft Toxicological Review of Formaldehyde Inhalation Assessment through the IRIS program for peer review by the National Research Council (NRC) and public comment in June 2010 (EPA 2010e). The draft assessment reviewed more recent research from animal and human studies on cancer and other health effects. The NRC released their review report in April 2011 (NRC 2011a). EPA’s draft assessment, which addresses NRC recommendations, was suspended in 2018. The draft assessment was resumed in March 2021 (EPA 2021e), and EPA currently is revising the assessment based on the results of external peer review.

C.4 Vehicle Emissions Standards

EPA and the California Air Resources Board (CARB) have established criteria pollutant emissions standards for vehicles under the Federal Clean Air Act (CAA). EPA and CARB have tightened these

emissions standards over time as more effective emissions-control technologies have become available.⁵ These stricter standards for LD vehicles (i.e., passenger cars and light trucks) and for HD vehicles are responsible for the declines in total criteria pollutant emissions from motor vehicles, as discussed in Chapter 4, Section 4.1.1, *Relevant Pollutants and Standards*. The EPA Tier 2 Vehicle & Gasoline Sulfur Program, which went into effect in 2004, established the CAA emissions standards that applied to MY 2004–2016 passenger cars and light trucks (EPA 2000c). Under the Tier 2 standards, manufacturers of passenger cars and light trucks were required to meet stricter vehicle emissions limits than under the previous Tier 1 standards. By 2006, U.S. refiners and importers of gasoline were required under the Tier 2 standards to manufacture gasoline with an average sulfur level of 30 ppm, a 90 percent reduction from earlier sulfur levels. These fuels enable post-MY 2006 vehicles to use emissions-control technologies that reduce tailpipe emissions of NO_x by 77 percent for passenger cars and by as much as 95 percent for pickup trucks, vans, and sport utility vehicles compared to 2003 levels. On April 28, 2014, EPA issued a Final Rule establishing Tier 3 motor vehicle emissions and fuel standards.⁶ The Tier 3 vehicle standards reduce both tailpipe and evaporative emissions from passenger cars, LD trucks, medium-duty passenger vehicles, and HDPUVs. Starting in 2017, Tier 3 sets new vehicle emissions standards and lowers the sulfur content of gasoline to 10 ppm, considering the vehicle and its fuel as an integrated system. The Tier 3 program phases out the Tier 2 vehicle emissions standards and replaces them with Tier 3 standards, which are being phased in over MYs 2017–2025 and will remain constant thereafter at the MY 2025 levels. The Tier 3 program requires emissions reductions from new passenger cars and light trucks of approximately 80 percent for NO_x and VOCs, 70 percent for PM, and 67 percent for SO₂. The Tier 3 gasoline sulfur standard makes emissions-control systems more effective for both existing and new vehicles and enables more stringent vehicle emissions standards (EPA 2014d). In 2024, EPA issued Tier 4 criteria pollutant standards for MY 2027–2032 LD vehicles and medium-duty vehicles (which NHTSA refers to as HDPUVs) in its recently published final rule.⁷

Figure C.4-1 illustrates current trends in travel and emissions from highway vehicles, not accounting for the impacts of the Proposed Action and alternatives (Chapter 4, Section 4.2, *Environmental Consequences*). Since 1970, aggregate emissions traditionally associated with vehicles have decreased substantially even as vehicle miles traveled (VMT) increased by approximately 194 percent from 1970 to 2022, as shown in Figure C.4-1. For example, NO_x emissions, due mainly to light trucks and HD vehicles, decreased by 83 percent between 1970 and 2022, despite increases in VMT. More recent trends show that changes in VMT are having a smaller and smaller impact on emissions because of stricter EPA standards for vehicle emissions and the chemical composition of fuels, even with additional growth in VMT (Smith 2002). This general trend will continue, to a certain extent, under any of the action alternatives. MSAT emissions will likely decrease in the future because of a 2007 EPA rule (EPA 2007). This rule limited the benzene content of gasoline beginning in 2011. It also limited exhaust emissions of hydrocarbons (many VOCs and MSATs are hydrocarbons) from passenger cars and light trucks when they are operated at cold temperatures. The cold-temperature standard was phased in from 2010

⁵ CAA Section 177 (42 U.S.C. 7507) gives states the option to adopt California's emissions standards provided that specified criteria in Section 177 are met. States that have done so sometimes are referred to as Section 177 states. In addition to California and Section 177 states' GHG emissions standards, discussed in Chapter 4, Section 4.1.3.3, *Vehicle Emissions Standards*, California and Section 177 states have enacted criteria pollutant emissions standards for vehicles under the CAA.

⁶ Control of Air Pollution from Motor Vehicles: Tier 3 Motor Vehicle Emission and Fuel Standards; Final Rule, 79 FR 23414 (April 28, 2014).

⁷ Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles; Final Rule, 40 CFR Parts 85, 86, 600, 1036, 1037, 1066, and 1068. Available at: <https://www.epa.gov/regulations-emissions-vehicles-and-engines/final-rule-multi-pollutant-emissions-standards-model>. (March 20, 2024).

through 2015. EPA projected that these controls will substantially reduce emissions of acetaldehyde, acrolein, benzene, 1,3-butadiene, and formaldehyde.

Figure C.4-1. Vehicle Miles Traveled Compared to Vehicle Emissions^{a,b,c}

Notes:

^a Because CO emissions are about 10 times higher than emissions of NO_x, SO_x, and VOCs and emissions of PM2.5 are about 10 times lower than emissions of NO_x, SO_x, and VOCs, the scales for CO and PM2.5 are proportionally adjusted to enable comparison of trends among pollutants.

^b Apparent increases in NO_x and PM2.5 emissions in 2002 are due to a change in methods made by EPA in 2012 from the MOBILE6.2 model to the MOVES model to calculate emissions for years 2002 and later (EPA 2013d).

^c The decrease in VMT in 2020 reflects the decreased amount of driving during the COVID-19 pandemic.

Sources: Davis and Boundy 2022; EPA 2023g; EIA 2023a.

VMT = vehicle miles traveled; VOC = volatile organic compound; NO_x = nitrogen oxides; CO = carbon monoxide;

PM2.5 = particulate matter 2.5 microns or less in diameter; SO_x = sulfur oxides

C.5 Methods

This section describes the approaches and methods used to estimate the impacts of the Proposed Action and alternatives in the EIS.

C.5.1 Overview

NHTSA uses the CAFE Compliance and Effects Modeling System (the CAFE Model) to estimate manufacturers' potential responses to new CAFE, CO₂, and HDPUV FE standards and to estimate various impacts of those responses. DOT's Volpe National Transportation Systems Center develops, maintains, and applies the model for NHTSA. The basic design of the CAFE Model is as follows: the system first estimates how vehicle manufacturers might respond to a given regulatory scenario, and from that potential compliance solution, the system estimates what impact that response will have on fuel

consumption, emissions, and economic externalities. NHTSA also uses EPA’s Motor Vehicle Emissions Simulator (MOVES) model to estimate “downstream” (tailpipe exhaust) emission factors, and uses Argonne National Laboratory’s Greenhouse gases, Regulated Emissions, and Energy use in Transportation (GREET) model to estimate emissions rates from fuel production and distribution processes (“upstream emissions”).

To analyze air quality and human health impacts, NHTSA used the CAFE Model to calculate the emissions of criteria pollutants and MSATs from passenger cars and light trucks that would occur under each CAFE standard alternative. Similarly, NHTSA calculated the emissions of criteria pollutants and MSATs from HDPUVs that would occur under each FE standard alternative. NHTSA then estimated the resulting changes in emissions under each action alternative by comparing emissions under that alternative to those under the relevant No-Action Alternative. The resulting changes in air quality and impacts on human health were assumed to be proportional to the changes in emissions projected to occur under each CAFE standard and HDPUV FE standard action alternative.

The air quality analysis accounted for manufacturers’ projected responses to CAFE, HDPUV FE, and CO₂ standards (including agreements some manufacturers have reached with California for MYs 2021–2026), zero-emission vehicle sales mandates in place in California and most Section 177 states,⁸ and NHTSA’s estimates of future fuel prices, market demand for fuel economy, and the cost and efficacy of fuel-saving technologies.⁹ The analysis also accounted for market responses, including demand for new LD vehicles and HDPUVs, scrappage of used LD vehicles and HDPUVs, and demand for travel (i.e., VMT), accounting for the rebound effect. The resultant change in emissions under each CAFE and HDPUV alternative would be the sum of the following components.

- Decreases in upstream emissions that result from decreases in gasoline consumption and, therefore, lower volumes of fuel production and distribution.
- Increases in upstream emissions that result from increases in electricity generation to power plug-in hybrid electric vehicles (PHEVs) and battery electric vehicles (BEVs).
- Increases in per-vehicle tailpipe emissions resulting from slight shifts in passenger car sales toward light trucks (because improving fuel economy produces larger fuel savings for light trucks than for passenger cars, and criteria pollutant and air toxic per-mile emission rates for light trucks are projected to remain higher than for passenger cars) and slightly greater reliance on older vehicles (which have higher per-mile emission rates than newer vehicles).
- Increases in emissions resulting from increased VMT due to the rebound effect.
- Decreases in tailpipe emissions resulting from increases in sales and use of PHEVs and BEVs.

As discussed in Chapter 2, *Proposed Action and Alternatives and Analysis Methods*, the air quality results presented in Chapter 4, *Air Quality*, including impacts on human health, are based on assumptions about the type and rate of emissions from the combustion of fossil fuels. In addition to tailpipe estimates from the Motor Vehicle Emission Simulator (MOVES4) (EPA 2023b),¹⁰ this analysis accounts for upstream emissions from the extraction, production, and distribution of fuels, including contributions from the

⁸ *Section 177 states* refers to the states that have adopted California’s criteria pollutant and GHG emissions regulations under Section 177 of the CAA (42 U.S.C. 7507).

⁹ For further information on the analysis of zero-emissions vehicles, see NHTSA 2023, 2024.

¹⁰ EPA’s MOVES model, described in Chapter 2, Section 2.5.1, *Downstream Emissions*, estimates emissions based on a variety of inputs, including vehicle type and age, fuel type and quality, operating conditions, and vehicle characteristics.

power plants that generate the electricity used to recharge electric vehicles (EVs) and from the production of the fuel burned in those power plants. Emissions and other environmental impacts from electricity production depend on the efficiency of the power plant and the mix of fuel sources used, sometimes referred to as the *grid mix*. In the United States, the current (2022) grid mix is composed of natural gas, coal, nuclear, hydroelectric, wind, other renewable energy sources, and oil. The largest sources of electricity are from natural gas (39 percent), followed by renewables (21 percent), coal (20 percent), and nuclear (18 percent) (EIA 2023w).

To estimate upstream emissions changes resulting from changes in downstream fuel consumption, the analysis uses emissions factors from the Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) model (version 2023 developed by the U.S. Department of Energy, Argonne National Laboratory) (ANL 2023). Upstream emission factors for gasoline, diesel, flex fuel (E85), and electricity in grams per million British thermal units (MMBtu) were taken from the GREET model for 2022 and then 2025–2050 in 5-year increments. NHTSA developed upstream emissions factors for air toxics that are consistent with EPA’s National Emission Inventory and tailpipe emissions factors from the MOVES4 model. A spreadsheet model was developed to adjust upstream emissions factors to account for the imported share of petroleum.

The analysis presented throughout this EIS assumes that the future EV fleet would charge from a grid whose mix is uniform across the country. As with gasoline, diesel, and E85, emissions factors for electricity were calculated for 2022 and then 2025–2050 in 5-year increments in GREET to account for projected changes in the national grid mix. The GREET model contains information on the intensities (amount of pollutant emitted per unit of electrical energy generated) that extend to 2050. To project the U.S. average electricity-generating fuel mix, this rulemaking uses a grid mix from the Electrification Futures Study, specifically the 2022 Standard Scenarios forecast (Mid-case, nascent technologies, current policies scenario), developed by the National Renewable Energy Laboratory (Murphy et al. 2021). The Mid-case scenario assumes central or median values for core inputs such as technology costs and fuel prices, moderately paced demand growth averaging 1.3 percent per year, and electricity sector policies as they existed in September 2022 (including the Inflation Reduction Act). Retrofits of natural gas and coal plants with carbon capture and storage technologies (nascent technologies) are assumed to become common (Gagnon et al. 2022).

C.5.2 Regional Analysis

Over the course of the development of recent CAFE EISs (NHTSA 2010, 2012, 2020, 2022) and the medium- and heavy-duty FE standards Phase 1 and 2 EISs (NHTSA 2011, 2016b), NHTSA received comments requesting that the agency consider the regional air quality impacts of these programs. NHTSA has included the following information about regional air quality impacts of the Proposed Action and alternatives in response to such comments and because the agency believes that such an analysis provides valuable information for the decision-maker, state and local authorities, and the public. Performing this analysis does not affect the agency’s conclusion that a general conformity determination is not required. While a truly local analysis (i.e., at the individual roadway level) is impractical for a nationwide EIS, NHTSA believes a regional emissions analysis still provides valuable information and is feasible for the scope of this analysis.

To assess regional differences in the impacts of the alternatives, NHTSA estimated net emissions changes for individual nonattainment and maintenance areas. The distribution of emissions is not uniform nationwide, and either increases or decreases in emissions can occur within individual nonattainment and maintenance areas. NHTSA focused on nonattainment and maintenance areas

because air quality problems have been the greatest in these areas. NHTSA's assessment emphasized areas that are in nonattainment or maintenance for ozone or PM_{2.5} because these are the criteria pollutants that are of greatest concern to human health. At present, there are no CO or NO₂ nonattainment areas. There are many areas designated as being in nonattainment for SO₂ or PM₁₀. There are also maintenance areas for CO, NO₂, PM₁₀, and SO₂. NHTSA did not quantify PM₁₀ emissions separately from PM_{2.5} because almost all the PM in the exhaust from LD vehicles and HDPUVs is PM_{2.5}. Appendix D, *Air Quality Modelling and Health Impacts Assessment*, provides emissions estimates for all nonattainment and maintenance areas for all criteria pollutants (except lead, as explained in Chapter 4, Section 4.1.1, *Relevant Pollutants and Standards*). On-road motor vehicles are a minor contributor to SO₂ emissions (less than 0.5 percent of national emissions, as noted above) (EPA 2020e) and are unlikely to affect the attainment status of SO₂ nonattainment and maintenance areas.

NHTSA's emissions analysis is national and regional but does not attempt to address the specific geographic locations of changes in emissions within nonattainment and maintenance areas. For example, there is limited evidence that EV use is disproportionately greater in areas with the worst traffic congestion (Section 8.3.3.3 of NHTSA 2020). Because hybrid EVs and PHEVs have lower tailpipe emissions compared to conventionally fueled vehicles, and BEVs have no tailpipe emissions, greater EV use in these areas could suggest that tailpipe emissions in urban nonattainment areas would be less than the analysis estimates. However, because of the complication and uncertainties associated with these local variations, NHTSA's emissions analysis does not assume any variation by vehicle type or fuel in the geographic distribution of VMT. In addition, EV charging location and time affects emissions from power plants by changing the demand for electricity in the region where charging occurs, for the duration of charging (Section 3.2.2.2, *Region-Specific Electricity Grid Impacts*). NHTSA's emissions analysis does not assume any variation in EV charging by location or time.

Emissions changes due to the rebound effect would occur from LD vehicles and HDPUVs operating on entire regional roadway networks; any emissions changes due to the rebound effect would be distributed throughout a region's entire road network and at any specific location would be uniformly proportional to VMT changes at that location. At any one location within a regional network, the resulting change in emissions would be small compared to total emissions from all sources surrounding that location (including existing emissions from traffic already using the road), so the localized impacts of the Proposed Action and alternatives on ambient concentrations and health impacts should also be small. The nationwide aggregated consequences of such small near-source impacts on ambient pollutant concentrations and health might be larger but are not feasible to quantify.

C.5.3 Analysis Periods

The longest averaging period for measuring whether ambient concentrations of a pollutant comply with the NAAQS is 1 year.¹¹ This air quality analysis considers emissions that would occur over annual periods, consistent with the NAAQS. To evaluate impacts on air quality, specific years must be selected for which emissions are estimated and impacts on air quality are calculated.

¹¹ Compliance with the ozone NAAQS is based on the average of the fourth highest daily maximum 8-hour concentration over a 3-year period; compliance with the 24-hour PM_{2.5} NAAQS is based on the average of the daily 98th-percentile concentrations averaged over a 3-year period; compliance with the annual PM_{2.5} NAAQS is based on the 3-year average of the weighted annual mean concentrations.

NHTSA selected calendar years that are meaningful for the timing of likely effects of the alternatives, as follows.

- **2035:** A near-term forecast year for passenger cars, light trucks, and HDPUVs; by 2035 manufacturers could be 4 years beyond a full response (MY 2031) to new CAFE standards and in the process of responding to the new FE standards for HDPUVs, with vehicles produced in MYs 2027 and beyond accounting for much of the on-road fleet's VMT.
- **2050:** A long-term forecast year; by 2050, vehicles produced in MYs 2027 and beyond will account for almost all of the on-road fleet's VMT, such that changes in year-over-year impacts would be determined primarily by VMT growth.

C.5.4 Incomplete or Unavailable Information

Where information in this analysis is incomplete or unavailable, NHTSA relies on CEQ regulations regarding incomplete or unavailable information.¹² As noted throughout this methods section, the estimates of emissions rely on models and forecasts that contain numerous assumptions and data that are uncertain. Examples of areas in which information is uncertain (and therefore may be incomplete or unavailable) include future emissions rates, vehicle manufacturers' decisions about vehicle technology and design, the mix of vehicle types and model years in the LD and HDPUV fleets, VMT projections, emissions from fuel refining and distribution, the future composition of the grid mix, and economic factors. The degree of uncertainty increases as projections extend farther into the future.

To support the information in this EIS, NHTSA used the best available models and supporting data. The models used for the EIS were subjected to scientific review and were approved by the agencies that sponsored their development. Nonetheless, there are limitations to current modeling capabilities. For example, uncertainties can derive from model formulation (including numerical approximations and the definition of physical and chemical processes) and inaccuracies in the input data (e.g., emissions inventory estimates).

Additional limitations are associated with the estimates of health impacts. To approximate the health impacts associated with each alternative, NHTSA used screening-level estimates of health impacts in the form of cases per ton of criteria pollutant emissions change. Changes in emissions of toxic air pollutants should also result in health impacts, but scientific data that would support quantification and monetization of these impacts are not available.

C.5.5 Allocation of Exhaust Emissions to Nonattainment Areas¹³

For each CAFE standard and HDPUV FE standard alternative, the CAFE Model provided national emissions estimates for each criteria air pollutant (or its chemical precursors) and MSAT. National emissions were allocated to the county level using VMT data for each county. EPA provided estimated passenger car, light truck, and HDPUV VMT data for all counties in the United States, consistent with EPA's National Emissions Inventory (NEI).¹⁴ VMT data used in the NEI were estimated from traffic counts taken by counties and states on major roadways, and therefore are subject to some uncertainty. These

¹² 40 CFR 1502.21(b).

¹³ In Section C.5.5, *Allocation of Exhaust Emissions to Nonattainment Areas*, and Section C.5.6, *Allocation of Upstream Emissions to Nonattainment Areas*, the term *nonattainment* refers to both nonattainment areas and maintenance areas.

¹⁴ The VMT data provided by EPA are based on data generated by the Federal Highway Administration.

EPA data were projected for 2032, the most representative year available in the EPA dataset. NHTSA used the estimates of county-level VMT from the NEI only to allocate nationwide total emissions to counties and not to calculate the county-level emissions directly. The estimates of nationwide total emissions are based on the national VMT data used in the CAFE Model.

NHTSA used the county-level VMT allocations, expressed as the fractions of national VMT that take place within each county, to derive the county-level emissions from the estimates of nationwide total emissions. Emissions for each nonattainment area were then derived by summing the emissions for the counties included in each nonattainment area. Many nonattainment areas comprise one or more counties, and because county-level emissions are aggregated for each nonattainment area, uncertainties in the county-level emissions estimates carry over to estimates of emissions within each nonattainment area. Over time, some counties will grow faster than others, and VMT growth rates will vary. EPA's estimate of county-level VMT allocation is constant over time, which introduces some uncertainty into the nonattainment-area-level VMT estimates for future years. Additional uncertainties that affect county-level exhaust emissions estimates arise from differences among counties or nonattainment areas in factors other than VMT, such as ambient temperatures, vehicle age distributions, vehicle speed distributions, vehicle inspection and maintenance programs, and fuel composition requirements. Because of these uncertainties, emissions in a particular nonattainment area may be overestimated or underestimated. The overall uncertainty increases as the projection period lengthens, such as for analysis year 2050 compared with analysis year 2035.

The geographic definitions of nonattainment and maintenance areas that NHTSA uses in this document came from the current *Green Book Nonattainment Areas for Criteria Pollutants* (EPA 2024d). For nonattainment areas that include portions of counties, NHTSA calculated the proportion of county population that falls within the nonattainment area boundary as a proxy for the proportion of county VMT within the nonattainment area boundary. Partial county boundaries were taken from geographic information system (GIS) files based on 2024 nonattainment area definitions. The population estimates utilized projections to the 2035 and 2050 analysis years at 1-kilometer resolution across the country (Gao 2020). This method assumes that per-capita VMT is constant in each county so that the proportion of countywide VMT in the partial county area reflects the proportion of total county population residing in that same area. This technique for allocating VMT to partial counties involves some additional uncertainty because actual VMT per capita can vary according to the characteristics of land use and urban development. For example, VMT per capita can be lower than average in urban centers with mass transit, and higher than average in suburban and rural areas where people tend to drive more (Cook et al. 2006; Eno Center for Transportation 2019).

The method for allocation of emissions to nonattainment areas is the same for all geographic areas and pollutants. Table C.5.5-1 lists the current nonattainment and maintenance areas for ozone and PM_{2.5} and their status and general conformity threshold. Areas for ozone and PM_{2.5} are listed because these are the pollutants for which nonattainment areas encompass the largest human populations. For the complete list of nonattainment and maintenance areas for all pollutants and standards, see Appendix D, *Air Quality Modelling and Health Impacts Assessment*.

Table C.5.5-1. Nonattainment and Maintenance Areas for Ozone and PM2.5

Nonattainment/Maintenance Area	Pollutant	Status ^a	General Conformity Threshold ^b

Notes:

^a Pollutants for which the area is designated in nonattainment or maintenance as of January 2024. For nonattainment areas, the status given is the severity classification as defined in 40 CFR 51.1303. Classifications in order of increasing ozone concentration are Marginal, Moderate, Serious, Severe 15, Severe 17, and Extreme. Where an area is nonattainment for more than one standard for the same pollutant, the more restrictive severity classification is shown.

^b Emissions thresholds in tons per year. In ozone nonattainment areas, the thresholds given are for the precursor pollutants VOC or NO_x; in PM2.5 nonattainment areas the thresholds represent primary PM2.5. Where an area is nonattainment for more than one standard for the same pollutant, the lowest applicable threshold is shown. Source: 40 CFR 93.153. These thresholds are provided for information only; a general conformity determination is not required for NHTSA's Proposed Action.

NO_x = nitrogen oxides; PM2.5 = particulate matter 2.5 microns or less in diameter; VOC = volatile organic compounds

C.5.6 Allocation of Upstream Emissions to Nonattainment Areas

For liquid and gaseous fuels, upstream emissions are generated when fuels used by motor vehicles are produced, processed, and transported. Upstream emissions are typically divided into four categories: feedstock recovery; feedstock transportation; fuel refining; and fuel transportation, storage, and distribution (TS&D). Feedstock recovery refers to the extraction or production of fuel feedstocks—the materials (e.g., crude oil) that are the main inputs to the refining process. In the case of petroleum, this is the stage of crude-oil extraction. During the next stage, feedstock transportation, crude oil or other feedstocks are shipped to fuel refineries. Fuel refining refers to the processing of crude oil into gasoline and diesel fuel. Fuel refining is the largest source of upstream emissions of criteria pollutants. Depending on the specific fuel and pollutant, fuel refining accounts for between 48 and 87 percent of all upstream emissions per unit of fuel produced and distributed (based on GREET version 2023). Commonly, TS&D refers to the movement of gasoline and diesel from refineries to bulk terminals, storage at bulk terminals, and transportation of fuel from bulk terminals to retail outlets.¹⁵ Emissions of pollutants at each stage are associated with expenditure of energy and with leakage or spillage and evaporation of fuel products. NHTSA has allocated upstream emissions to individual nonattainment areas to provide additional information in its regional air quality analysis to the decision-maker and the public, consistent with previous CAFE EISs (NHTSA 2010, 2012, 2020, 2022) and the heavy-duty fuel efficiency standards EISs (NHTSA 2011, 2016b). NHTSA made a number of assumptions for this analysis because of uncertainty over the accuracy of the allocation of upstream emissions. A similar analysis was performed for upstream emissions from electricity for transportation use, accounting for feedstock production and then electricity generation and transmission using a nationally representative grid mix (see Chapter 3, Section 3.2.2, *Electricity*, for a discussion on the environmental impacts).

To analyze the impacts of the alternatives on individual nonattainment areas, NHTSA allocated projected emissions data from the EPA 2016-based air quality modeling platform (EPA 2022e). These EPA data were projected for 2032, the most representative year available in the EPA dataset. NHTSA allocated changes in nationwide total emissions, for each of the four source categories separately, to individual nonattainment areas. The EPA modeling platform includes estimates of emissions of criteria and toxic pollutants by county and by source category. Because each of the four upstream emissions source categories represents a separate source category in the EPA modeling platform, it is possible to estimate the share of nationwide emissions from each category that occurs within each nonattainment area. This analysis assumes that the share of emissions from feedstock extraction and fuel refining allocated to each nonattainment area does not change over time, which means that emissions for these two source categories are assumed to change uniformly (in percentage terms) across that category nationwide as a result of each alternative.¹⁶ This analysis also assumes that the share of emissions from feedstock and fuel TS&D allocated to each nonattainment area can change over time based on the population forecast for each area.

¹⁵ Emissions that occur while vehicles are being refueled at retail stations are included in estimates of emissions from vehicle operation.

¹⁶ NHTSA incorporated the feedstock recovery and feedstock transportation stages in this EIS. Emissions from the feedstock recovery and feedstock transportation stages are small relative to total upstream and tailpipe emissions and do not have a substantial effect on the EIS results.

C.5.7 Health Impacts

This section describes NHTSA’s approach to providing quantitative estimates of adverse health impacts of conventional air pollutants associated with each CAFE standard and HDPUV FE standard alternative. In this analysis, NHTSA quantified the impacts on human health anticipated to result from the changes in pollutant emissions and related changes in human exposure to air pollutants under each alternative. NHTSA evaluated the changes to several health outcomes associated with criteria pollutant emissions. Table C.5.7-1 lists the health outcomes NHTSA quantified. This method estimates the health impacts of each alternative for each analysis year, expressed as the number of additional or avoided adverse health outcomes per year. Health outcomes are calculated for each primary pollutant (NO_x, directly emitted PM2.5, and SO₂) and expressed as adverse health outcomes increased per ton of increased emissions or as adverse health outcomes avoided per ton of reduced emissions. Each primary pollutant has a specific factor related to its quantifiable health impacts expressed as incidence of impacts per ton of emissions. The general approach to calculating the health outcomes associated with each alternative is to multiply these factors by the estimated annual change in emissions of that pollutant and to sum the results of these calculations for all pollutants. This calculation provides the total health impacts that would result under each CAFE standard and HDPUV FE standard alternative.

Table C.5.7-1. Human Health and Welfare Impacts of PM2.5

Impacts Quantified	Impacts Excluded from Quantification ^a
Adult premature mortality	Chronic bronchitis (age >26)
Infant mortality	Emergency room visits for cardiovascular effects
Acute bronchitis (age 8–12)	Strokes and cerebrovascular disease (age 50–79)
Hospital admissions: respiratory (all ages) and cardiovascular (age >26)	Other respiratory effects (e.g., pulmonary function, non-asthma emergency room visits, nonbronchitis chronic diseases, other ages and populations)
Emergency room visits for asthma	Cardiovascular effects other than those listed
Nonfatal heart attacks (age >18)	Reproductive and developmental effects (e.g., low birth weight, preterm births)
Lower (age 7–14) and upper (age 9–11) respiratory symptoms	Cancer, mutagenicity, and genotoxicity effects
Minor restricted-activity days (age 18–65)	--
Lost work days (age 18–65)	--
Asthma exacerbations (asthmatics age 6–18)	--

Notes:

^a EPA excluded these effects because of insufficient confidence in available data or methods, or because current evidence is only suggestive of causality or there are other significant concerns over the strength of the association.

Source: EPA 2018c.¹⁷ See this source for more information related to the affected ages included in the analysis. For related information see also EPA 2019b and EPA 2022i.

PM2.5 = particulate matter 2.5 microns or less in diameter; EPA = U.S. Environmental Protection Agency

¹⁷ EPA updated this document in 2023. However, the 2023 document does not include mobile source sectors, which are an important part of NHTSA’s analysis. EPA recommended that NHTSA continue to use the older document for consistency until EPA publishes updated information for mobile sources.

In calculating the health impacts of emissions increases, NHTSA estimated only the PM_{2.5}-related human health impacts expected to result from population exposure to atmospheric concentrations of PM_{2.5}. Directly emitted PM_{2.5} is included in the analysis, as are NO_x and SO₂ as precursor emissions that contribute to secondary formation of PM_{2.5} (PM_{2.5} that is not directly emitted but rather is formed by chemical reactions in the atmosphere). NO_x and VOC emissions would also increase ozone formation and the health effects associated with ozone exposure, but there are no incidence-per-ton estimates for NO_x and VOCs because of the complexity of the atmospheric air chemistry and nonlinearities associated with ozone formation. This analysis does not include any health impacts resulting from greater population exposure to other criteria air pollutants and air toxics because there are not enough data available to quantify these impacts.

C.5.7.1 Quantified Health Impacts

The incidence-per-ton factors represent the total human health benefits due to a suite of PM-related health impacts for each ton of emissions reduced. The factors are specific to an individual pollutant and source. The PM_{2.5} incidence-per-ton estimates apply to directly emitted PM_{2.5} or its precursors (NO_x and SO₂). NHTSA followed the incidence-per-ton technique used in EPA's PM_{2.5} NAAQS Regulatory Impact Analysis (RIA) (EPA 2013a), Ozone NAAQS RIA (EPA 2010b), Portland Cement National Emission Standards for Hazardous Air Pollutants RIA (EPA 2010c), NO₂ NAAQS RIA (EPA 2010d), and *Estimating the Benefit per Ton of Reducing PM_{2.5} Precursors from 17 Sectors* (EPA 2018c).^{18,19} NHTSA included additional updates given in Wolfe et al. (2019).

Table C.5.7-1 lists the quantified PM_{2.5}-related benefits captured in those benefit-per-ton estimates, and potential PM_{2.5}-related benefits that were not quantified in this analysis. The benefits estimates use the concentration-response functions²⁰ as reported in the epidemiology literature.²¹

EPA developed national per-ton estimates for selected pollutants emitted through stationary and mobile activity (EPA 2018c;²² Wolfe et al. 2019). Because the per-ton values vary between emissions source and pollutant, the total health impacts were derived by multiplying the stationary per-ton estimates by total upstream emissions and the mobile per-ton estimates by total mobile emissions. NHTSA's estimate of PM_{2.5} benefits is, therefore, based on the total direct PM_{2.5} and PM_{2.5}-related precursor emissions controlled by sector and multiplied by this per-ton value.

¹⁸ EPA refers to this technique as the "benefit per ton" method for estimating the health benefits of reduced emissions, and NHTSA follows this terminology in this appendix. However, this technique applies equally to estimating the additional health outcomes from increased emissions.

¹⁹ EPA updated this document in 2023 for 21 stationary EPA source sectors: https://www.epa.gov/system/files/documents/2021-10/source-apportionment-tsd-oct-2021_0.pdf.

²⁰ Concentration-response functions measure the relationship between exposure to pollution as a cause and specific outcomes as an effect (e.g., the incremental number of hospitalizations that would result from exposure of a population to a specified concentration of an air pollutant over a specified period).

²¹ The complete method for creating the benefit-per-ton estimates used in this analysis is provided in *Estimating the Benefit per Ton of Reducing PM_{2.5} Precursors from 17 Sectors* (EPA 2018c) and Fann et al. (2009). Since the publication of Fann et al. (2009), EPA no longer assumes that there is a threshold in PM-related models of health impacts.

²² EPA updated this document in 2023. However, the 2023 document does not include mobile source sectors, which are an important part of NHTSA's analysis. EPA recommended that NHTSA continue to use the older document for consistency until EPA publishes updated information for mobile sources.

PM-related mortality reductions provide most of the benefit in each benefit-per-ton estimate. EPA's methodology has been updated, see recent *Multi-Pollutant Emissions Standards for Model Years 2027 and Later Light-Duty and Medium-Duty Vehicles* (LMDV rule), but due to time constraints NHTSA was unable to update this analysis for the Final EIS to be consistent with EPA's LMDV rule. The following description of NHTSA's approach is based on EPA's earlier methodology from the *Revised 2023 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions Standards* (EPA 2021f). EPA bases its benefits analyses on peer-reviewed studies of air quality and health effects. EPA calculated the premature mortality-related effect coefficients that underlie the benefits-per-ton estimates from an epidemiology study that examined a large population cohort—the American Cancer Society (ACS) cohort (Krewski et al. 2009). EPA estimated the benefits of changes in PM_{2.5} and ozone based on information drawn from EPA's 2019 PM_{2.5} and 2020 Ozone ISAs, which were reviewed by the Clean Air Science Advisory Committee and the public (EPA 2019b, 2020a). These benefit-per-ton estimates are based on the review of the EPA 2009 PM ISA and 2012 PM ISA Provisional Assessment and include a mortality risk estimate derived from the Krewski et al. (2009) analysis of the ACS cohort and nonfatal illnesses consistent with benefits analyses performed for the analysis of the final EPA Tier 3 Vehicle Rule, the final EPA 2012 PM NAAQS Revision, and the final EPA 2017–2025 LD Vehicle GHG Rule.

The benefits of mortality reductions do not occur in the year of analysis. Instead, EPA's method assumes that there is a cessation lag—that is, the benefits are distributed across 20 years following the year of exposure (the emissions analysis year). The benefits-per-ton estimates used in this analysis are based on the mortality health outcome factors given in Table C.5.7-1. The benefit-per-ton estimates are subject to several assumptions and uncertainties:

- The benefit-per-ton estimates incorporate projections of key variables, including atmospheric conditions, source level emissions, population, health baselines, and incomes. These projections introduce some uncertainties to the benefit-per-ton estimates.
- The benefit-per-ton estimates do not reflect local variability in population density, meteorology, exposure, baseline health incidence rates, or other local factors that might lead to an overestimate or underestimate of the actual benefits of controlling fine particulates (PM_{2.5}). Emissions changes and benefit-per-ton estimates alone are not a precise indication of local or regional air quality and health impacts because there could be localized impacts associated with the Proposed Action and alternatives. Because the atmospheric chemistry related to ambient concentrations of PM_{2.5}, ozone, and air toxics is very complex, full-scale photochemical air quality modeling is necessary to control for local variability. Full-scale photochemical modeling provides the needed spatial and temporal detail to estimate changes in ambient levels of these pollutants and their associated impacts on human health and welfare. This modeling provides insight into the uncertainties associated with the use of benefit-per-ton estimates. NHTSA conducted a photochemical modeling analysis for the Final EIS using the same methods as in the CAFE Final EISs (NHTSA 2010, 2012, 2020, 2022) and the HD FE Standards Phases 1 and 2 Final EISs (NHTSA 2011, 2016b). Using the same approach the agency used for the *Final Supplemental Environmental Impact Statement for Model Year 2024–2026 Corporate Average Fuel Economy Standards* (NHTSA 2022) photochemical analysis, NHTSA conducted the photochemical modeling analysis for this EIS using a 12-kilometer (7.5-mile) by 12-kilometer grid cell size in accordance with EPA guidance (EPA 2018f), making use of the most recent EPA emissions information that is based on a 12-kilometer by 12-kilometer grid cell size. Appendix E, *Air Quality Modeling and Health Impacts Assessment*, discusses the photochemical modeling analysis and results.
- NHTSA assumed that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality. This is an important assumption, because PM_{2.5} produced via

transported precursors emitted from stationary sources might differ significantly from direct PM_{2.5} released from diesel engines and other industrial sources. However, there are no clear scientific grounds to support estimating differential effects by particle type.

- NHTSA assumed that the health impact (concentration-response) function for fine particles is linear within the range of ambient concentrations under consideration. Therefore, the estimates include health benefits from reducing fine particles in areas with varied concentrations of PM_{2.5}, including regions that are in attainment for the fine-particle standard and those that do not meet the standard, down to the lowest modeled concentrations.
- The following uncertainties, among others, are associated with the health impact functions. These uncertainties could underestimate or overestimate benefits.
 - Within-study variability (the precision with which a given study estimates the relationship between air quality changes and health impacts)
 - Across-study variation (different published studies of the same pollutant/health effect relationship typically do not report identical findings, and in some cases the differences are substantial)
 - Application of concentration-response functions nationwide (does not account for any relationship between region and health impact to the extent that there is such a relationship)
 - Extrapolation of impact functions across population (NHTSA assumed that certain health impact functions applied to age ranges broader than those considered in the original epidemiological study)
- NHTSA was unable to quantify several health-benefits categories because of limitations associated with using benefit-per-ton estimates, several of which could be substantial. Because NO_x and VOCs are also precursors to ozone, reductions in NO_x and VOC emissions would also reduce ozone formation and the health effects associated with ozone exposure. Unfortunately, there are no benefit-per-ton estimates because of the complexity of the atmospheric air chemistry and nonlinearities associated with ozone formation. The PM-related benefit-per-ton estimates also do not include any human welfare or ecological benefits because of limitations on the availability of data to quantify these impacts of pollutant emissions.

Because of these uncertainties, it is not possible to draw conclusions about whether the benefit-per-ton values are underestimated or overestimated. For further information about the uncertainties associated with the benefit-per-ton values see Appendix E, Section E.4.3.3, *Attributes, Limitations, and Uncertainties*. The RIA for the 2012 PM_{2.5} NAAQS (EPA 2013a) provides more information about the overall uncertainty in the estimates of the benefits of reducing PM_{2.5} emissions.

Tables C.5.7-2a–e list the incidence-per-short-ton estimates for PM-related health impacts (derived by the process described in this section). For the analysis of direct and indirect impacts (Chapter 4, Section 4.2, *Environmental Consequences*) NHTSA used the values shown here for 2030 (Section C.5.3, *Analysis Periods*) to estimate impacts in 2035 and 2050.

NO_x = nitrogen oxides; PM2.5 = particulate matter 2.5 microns or less in diameter; SO_x = sulfur oxides; HDPUV = heavy-duty pickup trucks and vans

The EPA incidence-per-ton estimates shown in Tables C.5.7-2a–e are national averages and account for effects of upstream and downstream emissions separately. However, they do not reflect localized variations in emissions, population characteristics, or exposure to pollutants. Most upstream emissions are released from elevated points (e.g., tall stacks at refineries and power plants) and disperse widely before reaching ground level. The population in a large geographic region could be affected, but pollutant concentrations generally would be relatively low at any one location. On the other hand, concentrations very close to an upstream source that releases emissions at a relatively low elevation could be greater. The actual health impacts from human exposure at any particular location would vary with emissions, local meteorology and topography, and population characteristics.

Unlike most upstream emissions, downstream emissions occur across the roadway system and are released at or near ground level. Populations located near roadways could experience relatively greater pollutant levels because the short distance from the roadway allows less pollutant dispersion to occur. Near-road pollutant levels could be less in areas with greater EV adoption because EVs do not contribute tailpipe emissions. As with upstream emissions, the actual health effects from human exposure at any particular location would vary with emissions, local meteorology and topography, and population characteristics. Because of these variations, the actual change in health impacts per ton of emissions change could be larger or smaller at any particular location than the values in Tables C.5.7-2a–e.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-2. Changes in Emissions from U.S. Passenger Cars and Light Trucks by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Particulate Matter (PM_{2.5}), 2050

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-3. Changes in Emissions from U.S. Passenger Cars and Light Trucks by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Sulfur Oxides (SO₂), 2035

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-4. Changes in Emissions from U.S. Passenger Cars and Light Trucks by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Sulfur Oxides (SO₂), 2050

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-10. Changes in Emissions from U.S. Passenger Cars and Light Trucks by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Carbon Monoxide (CO), 2050

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants;

<http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-19. Changes in Emissions from U.S. Passenger Cars and Light Trucks by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Diesel Particulate Matter (DPM), 2035

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-20. Changes in Emissions from U.S. Passenger Cars and Light Trucks by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Diesel Particulate Matter (DPM), 2050

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:
^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.
^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.
^c Positive values are emissions increases; negative values are emissions decreases.
 EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM_{2.5} = particulate matter less than 2.5 microns in size; PM₁₀ = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-23. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Particulate Matter (PM2.5), 2035

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-24. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Particulate Matter (PM2.5), 2050

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-25. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Sulfur Oxides (SO₂), 2035

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-26. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Sulfur Oxides (SO₂), 2050

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-27. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Nitrogen Oxides (NOx), 2035

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-28. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Nitrogen Oxides (NOx), 2050

Yuma, AZ	PM10 (1987 24-hour)	Nonattainment, Moderate	100	0	-0.01	-0.23	-0.33	-0.82

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-29. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Volatile Organic Compounds (VOCs), 2035

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-30. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Volatile Organic Compounds (VOCs), 2050

Yuma, AZ	PM10 (1987 24-hour)	Nonattainment, Moderate	100	0	-0.08	-1.23	-1.85	-4.55

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "—" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-31. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Carbon Monoxide (CO), 2035

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-32. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts—Carbon Monoxide (CO), 2050

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "—" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-33. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Acetaldehyde, 2035

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-34. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Acetaldehyde, 2050

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Appendix D Air Quality Nonattainment Area Results

Notes:

^a Nonattainment or maintenance status as of 2/1/2024. Source: EPA, The Green Book Nonattainment Areas for Criteria Pollutants; <http://www.epa.gov/airquality/greenbook/>. "--" indicates that no severity classification has been established for the NAAQS pollutant.

^b Emissions thresholds in tons per year. Where the threshold differs by precursor pollutant, the smallest of the precursor thresholds is shown. These thresholds are provided for information only; a general conformity determination is not required for the Proposed Action. Source: 40 CFR 93.853.

^c Positive values are emissions increases; negative values are emissions decreases.

EPA = U.S. Environmental Protection Agency; NAAQS = National Ambient Air Quality Standard; CO = carbon monoxide; NO₂ = nitrogen dioxide; PM2.5 = particulate matter less than 2.5 microns in size; PM10 = particulate matter less than 10 microns in size; SO₂ = sulfur dioxide.

Table D-37. Changes in Emissions from U.S. Heavy-Duty Pickup Trucks and Vans by Nonattainment or Maintenance Area and Alternative, Direct and Indirect Impacts--Benzene, 2035
